Index Supplement to The Sanitary Record, *July 4th*, 1901

THE

Sanitary Record

AND

JOURNAL OF SANITARY & MUNICIPAL ENGINEERING.

JANUARY, 1901—JUNE, 1901. VOL. XXVII.

LONDON:
THE SANITARY PUBLISHING COMPANY, LIMITED, 5, FETTER LANE, E.C.

INDEX TO VOLUME XXVII.

ABATTOIRS, In Favour of, 315
Adulteration of Food and Drink in Manchester, 15 of Supp., February
Adulteration, The Other Side of the Question, 3 of Supp., January
Air We Breathe, The, 294
Alcoholism as a Factor in Insanity, 21 of Supp., March
Ale and Beer in the Sixteenth Century, 13 of Supp., February
Alleged Insanitary Condition of H.M.S. Britannia, The, 271
Analysis, The Value of, 558
Annual Reports, 177, 206, 238, 291, 317, 469, 561
Antiseptics in Foodstuffs, 12 of Supp., February
Architect's Utopia, An, 498
Arsenical Poisoning by Beer, 13 of Supp., February
Arsenical Poisoning in Crewe in 1900, Report on an Outbreak of, by Dr. Alfred Greenwood, 145
Arsenic Gets into Malt and Hops, How, 14 of Supp., February
Arsenic in Beer, 69, 91
Arsenic in Beer and Food, 12 of Supp., February
Arsenic in Food and Drink, 23 of Supp., March

BACTERIAL Treatment on Bacterial Lines, General Suggestions as to, by W. J. Dibdin and C. C. Smith, 375
Bakeries in India, Insanitary, 466
Baths for Bloomsbury, New Public, 560
Beer, Arsenical Poisoning by, 13 of Supp., February
Beer, Arsenic in, 69
Beer Poisoning Question, The, 52
Birmingham in 1900, The Health of, 121
Birth-rate, The Declining, 497
Boston Rural District Council and its M.O.H., 271
Building Trades Exhibition, 354, 379, 403, 428

CALCUTTA, The Extension of, 477
Camp and Barracks Sanitation, 10
Canada as a Source of Food Supply, 46 of Supp., June
Cases in Court (*see* Law Cases)
Cheese as a Food, 16 of Supp., February
Cheese, Danger in, 20 of Supp., March
Chinese Prejudice in Sanitary Matters, 471
Chloros Distributor, The, 366
Cleansing Backyards, 203
Cleansing Superintendents, Asociation of, Meeting at Sheffield, 426
Cleansing Work in Aberdeen, 558
Clothing and Disease, 562
Coffee, Adulteration of, 16 of Supp., February
Coffee as a Disinfectant, 440
COMING MUNICIPAL MEN :—
Ball, Geo., 378
Fowler, Frank, 115
Golder, T. C., 25
Compoboard, The Uses of, 103
Condensed Milk, The Value of, 40 of Supp., May
Construction of Roads, Paths, and Sea Defences, The, by Frank Latham, C.E., 487, 511, 535
Cookery, *de Luxe*, 44 of Supp., June
Cookery Exhibition, Forthcoming, 29 of Supp., April
Cooking Powders are "Cooked," How, 45 of Supp., June
Cooking, The Chemistry of, 19 of Supp., March
CORRESPONDENCE :—
A Clean Bill of Health, 36, 55, 71
A Correction, 207
A Curiosity in Sanitary Drainage Work, 54
A Good Record, 207, 250
Automatic Regulation of Bacteria Beds, 478
Boer Bullets, Are they Poisonous? 97
Crime in Liverpool, Virtue in London, 478
Dirty Public Vehicles, 478
Factory *v.* Home-made Clothing, 478, 503, 521
National Honours for Public Health Officials, 553
Nuisances from Tanyards, 521
Sanitas Sanitatum Omnia Sanitas, 541
Scavenging in Cape Town, 541
School Slates and Diphtheria, 503
Street Cleaning and Scavengers. 144
Successful Sewage Treatment, 503
Tar Paving for Footpaths, 340
The Artificial Colours in Sweets, 71
The Cup of the Sacrament, 71
The Housing of the Working Classes, 325
The Institution of Civil Engineers, 114, 144
The Plumbers' Company and the Registration of Plumbers, 358, 413
The Reeves System of Sewer Ventilation, 207, 208
The Rural Housing Problem, 359
Tuberculous Disease of Cows, 72
What Constitutes a Sanitary Inspector? 184
Cow Byres, the Sanitation of, 460
Crematorium, The First Municipal, 29

DAIRIES, The Supervision of, &c., by J. R. Kaye, 405
Diphtheria, How to Check, 23
Disinfection, Mechanical Aids to, 270
Domestic Sanitation, Problems of, 268
Drain Tester, A New, 169
Dust Destructors, 269

ELECTRICITY, Public Lighting by Gas and, by W. J. Dibdin, F.I.C., F.C.S., 1, 21, 111, 135, 223, 263, 423, 551
Electric Tramways and Asphalt Pavements, 5
Engineers, Association of Municipal and County, 257, 540
Annual Meeting at Leicester, 554
Engineers, Institution of Civil, The "James Forrest" Lecture, 383
Engineers, Society of, 127, 199, 224, 247, 495, 539
Enteric Fever amongst Armies in the Field, A Suggested Method of Preventing Water-borne, 63, 87
Epidemiological Society, 202
Essex, Insanitary, 206

FACTORY Inspectors, The Appointment of, 559
Feeding of Infants, The, 19 of Supp., March
Filter Cloth, An Improved, 7
Fish Unfit for Food, 4 of Supp., January
Food Adulteration in its Relation to the Public Health, 35 of Supp., May
Food Adulteration in Wilts, 497
Food Adulteration, Prevalent Processes of, 41 of Supp., June
Food and Drug Inspection in Massachusetts, 22 of Supp , March
Food Inspection, Unsatisfactory Methods of, 5 of Supp., January
Food in the County of London, Inspection of, 118
Food Values in Practical Life, 44 of Supp., June
Formic Fumigator, A New, 320

GAS and Electricity, Public Lighting by, by W. J. Dibdin, F.I.C., F.C.S., 1, 21, 111, 135, 223, 263, 423. 551
General, 16. 41, 58, 83, 106, 130, 153, 172, 193, 218, 242, 260, 282, 305, 329, 347, 371, 395, 418, 436, 457, 481, 506, 530, 548, 570
Glucose and Adulterated Syrup, 28 of Supp., April
Gluten Flour and Bread, 11 of Supp., February

HEALTH of London County, The, 26
Heredity as a Factor in the Causation of Tuberculosis, 96
Honey as a Food, 30 of Supp., Apri
Hospitals Commission Report, The, 98
House Refuse, The Collection of, by A. Taylor Allen, 28
Housing of the Poor, The, 68
Housing of the Poor in Rural Districts, 116
Housing of the Poor Problem in the Metropolis, The, 495

PUBLIC LIGHTING BY GAS & ELECTRICITY

By W. J. Dibdin, F.I.C., F.C.S.,
Late Chemist and Superintending Gas Examiner to the Metropolitan Board of Works and the London County Council.

(*Continued from page 561.*)

CHAPTER XV.—ELECTRO-MOTORS.

The different types of electric generators and the character of the currents they generate having now been described, we have still to consider how the power expended in the generation of the current by forcibly revolving the armature of the generator may be regained at some distant place, by conducting the current thence along copper wires and causing it to flow through a motor, whereby its armature is set in motion with almost the same force as that applied to the armature of the generator to produce the current, the loss of power being due mainly to the resistance of the conductors opposing the flow of the current, but also to several other causes, such as the friction of the armature spindles on their bearings, &c. Continuous-current motors are constructed on exactly the same lines as generators.

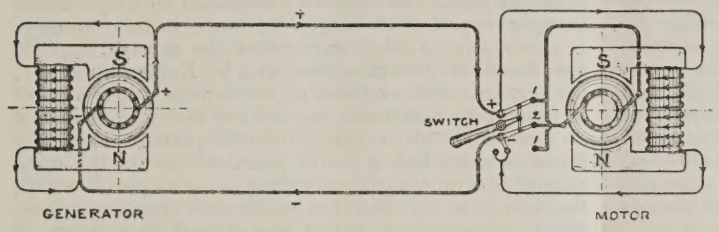

Fig. 23.

In a generator the coils of the armature cut through the lines of force in a magnetic field, causing magnetic lines of force to travel round the coils in opposition to those of the magnetic field, and a current of electricity to flow through them.

In a motor a current of electricity magnetises the field magnets, thus producing a magnetic field in which the armature is suspended, and a current of electricity at the same time flows through the coils of the armature causing magnetic lines of force to travel round them, which, by setting themselves in opposition to those of the magnetic field, impart rotation to the armature.

Fig. 23 shows the manner in which the current from the generator is made to flow through the motor by connecting the two brushes of the former with those of the latter.

In the motor as well as in the generator a portion of the current flows through the coils of the field magnets, while the rest flows through those of the armature.

Since by passing a current of electricity through a conductor magnetic lines of force are made to circle round it in either direction, according to which end the current is made to enter the conductor, it is obvious that if a conductor is suspended in a constant magnetic field and a current be sent through it, entering first at one end, then at the other, the lines of force, by circling round the conductor, first in one direction, then in another, will cause it to move in opposite directions. By this means the armature of a motor can be made to rotate in either direction and reversed at will, the manner in which this is effected being shown in the diagram.

By means of a double-pole switch connected with the positive and negative brushes of the generator, the brushes of the motor can be differently connected with those of the generator, so that either becomes positive or negative, and the current is thereby made to flow through the coils of the armature in either direction.

The current flowing through the coils of the field magnets may not be reversed, however, as the poles must always remain constant.

Single-phase alternating-current motors are also constructed on exactly the same lines as the generator; that is, the field magnets are excited separately by a continuous current flowing through their coils, while the armature is supplied with alternating current from the generator. (See Fig. 24.)

It is essential in these machines that the motor should run at exactly the same speed as the generator if both machines have an equal number of poles, and faster or slower if the motor has fewer or more poles than the generator, and in proportion to the number of poles in both machines. The poles of the field magnets remain constant, whereas the current in the coils of the armature is constantly changing.

At a certain moment one set of coils is opposite the N poles, and the other set opposite the S poles, with the current flowing through them in opposite directions, so that they both tend to impart rotation to the armature in one direction only.

Next instant the current in the coils is reversed, and in order that the rotation of the armature may continue in the same direction the coils must have traversed the space which divides a N pole from a S Pole, so that those coils which were fomerly opposite the N poles are now opposite the S poles, and those coils which were opposite the S poles are now opposite the N poles. That is to say, a coil being opposite a N pole with the current flowing momentarily through it towards the onlooker tends to impart a clockwise rotation to the armature. Next instant the current flows away from the onlooker, and if the coil be still opposite a N pole it will drive the armature back again, or in an opposite direction. As the current changes, therefore, the coil must have travelled as far as the neighbouring S pole,

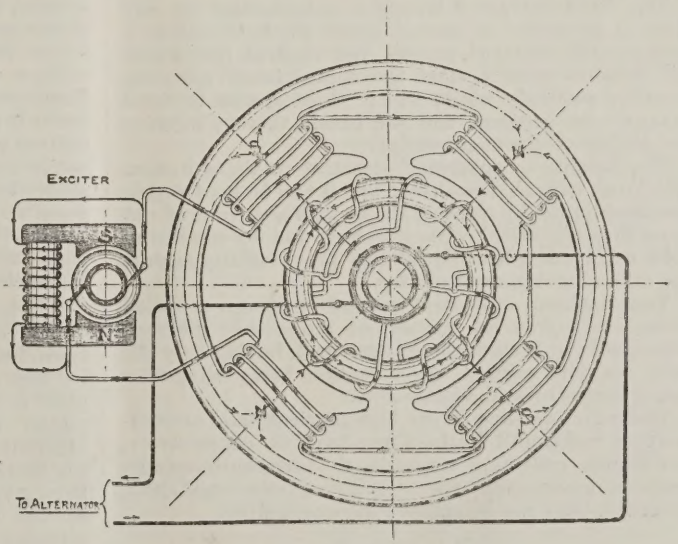

Fig. 24

so that the armature may continue rotating in the same direction, otherwise it will simply oscillate backwards and forwards.

In order that the motor may work, the armature must traverse the space dividing a N from S pole with the same frequency as the current changes from positive

to negative. To start the motor, the armature must be first revolved by hand, or by any other means, until the necessary speed is attained, when it will continue revolving as long as it is supplied with current, but it is liable to stop if a heavy load is suddenly put on.

In the case of small motors a portion of the alternating current may be converted into a pulsating continuous current by means of a commutator on the armature spindle, with which the magnets can be sufficiently excited.

The larger motors are usually built with a small continuous-current generator on the armature spindle for exciting the field magnet. To start these motors the small generator may be made to work as a motor by supplying it with continuous current from an accumulator until the requisite speed is imparted to the armature, when the accumulator may be switched off, and the motor then generates its own continuous current for exciting the field magnets, with which, too, the accumulator may be re-charged. Two and three-phase alternating-current motors may also be worked on this principle, and they have the advantage over single-phase motors in being self-starting, at least when unloaded.

In recent years single and polyphase alternating-current motors have been devised and constructed which work, although not well, on the same principle as continuous-current motors; that is to say, the alternating current flows through the coils of the field magnets, and magnetises them at the same time as through the coils of the armature, the use of a commutator being thus, of course, necessary.

The cores of the field magnets must be specially constructed, having alternate layers of very thin sheets of special soft iron and thin insulating material, so as to obviate as much as possible the loss of power that magnetising them alternately in opposite directions entails; for electro-magnets with cores of very soft iron retain only a very small portion of their magnetism, or none at all, after the current ceases to flow through their coils, whereas those having steel cores retain a considerable portion of their magnetism.

These motors are self-starting under full load, and they can be run at any speed, independently of that at which the generator runs.

The disadvantage of having a commutator on any class of generator or motor lies in the fact that as a commutator segment crosses the neutral line where the brushes press against the commutator, opposing currents suddenly meet, which cause sparks to form between the segment and the brush, thereby injuring the surface of the commutator.

The liability to sparking is greatest on those motors which run in both directions; but it can be kept within practical limits by working them with a current of not more than about 500 volts pressure, and by the use of thick carbon brushes adjusted to press radially against the surface of the commutator.

The modern alternating-current motors, so-called *induction motors* are worked on an entirely different principle from those hitherto described, having only the field magnets excited, the armature being altogether disconnected from the generator.

These motors have a very high efficiency and are self-starting under full load. They have no commutator, but simple collecting rings on the armature spindle become necessary if the speed requires regulating, otherwise they can be entirely dispensed with.

(To be continued.)

Mr. W. W. E. Fletcher, M.B., Inspector of the Local Government Board, recently attended at the Ormskirk Rural District Council offices, to conduct an inquiry as to extra borrowing powers for the enlargement of the infectious hospital.

SEWAGE DISPOSAL IN CALCUTTA.

By A. E. Silk,

Member of the Institute of Civil Engineers, Member of the Sanitary Institute, Sanitary Engineer, Bengal.

CHAPTER I.—Introductory.

In the author's pamphlet, "Recent Methods of Sewage Disposal in England," published two years ago, after he had had an opportunity of studying the all-important subject of sewage disposal in the country where it had advanced with such strides towards success within recent years, the lines were indicated on which it was thought experiments might be made in this country. It was shown in what particulars the sewage disposal question in India differs from that in England, namely, the concentrated condition of the sewage and its want of freshness; and it was pointed out that there must be no mere laboratory experiments with perhaps artificially made sewage, but a really practical one in the open ground of a municipality, dealing as far as possible with the sewage as it is found in public and private latrines. The Government of Bengal was pleased to approve of these suggestions, and instructions were issued to make the necessary designs, which were duly sanctioned and carried out. Fortunately at that time a new latrine for the native warders was required in the Presidency Gaol, and it was in the garden of the gaol that what is believed to be the first systematic experiment of the disposal o sewage by Nature's methods was carried out. In 189[illegible] a rough experiment had been made in the Garden Reach Municipality, but it was not a success for the reasons that will be given later on; an experiment was also made in Quetta in 1898 by Major Melville, R.A.M.C.,* but it was only continued for three months and no chemical analyses were made; it is understood, too, that a trial was also given to the biological system of sewage purification for the same period in 1899 in Simla, with results which satisfied the Local Authorities. Reasons were stated in the pamphlet referred to above, which led the author to think that the only practicable system for India was that known as the Septic Tank or Exeter system, and it was on these lines that the experiment was conducted; this was also the system, it is believed, that was adopted in the experiments referred to above. In India the sewage that has to be dealt with consists of solid fæces, urine, and sullage water — that is, the water used in cooking. There are practically no manufacturing wastes, and bath water is reduced to a minimum, as the majority of the natives of this country prefer to bathe in tanks or rivers out in the open. In the majority of cases the sewage is nearly twenty-four hours old before it reaches the disposal works, and on this question of the age of the sewage it will be instructive to quote the remarks made on page 434 of the Report of the State Board of Health of Massachusetts for 1898:—

"It is evident that, when this mixture of filth and organic matters of all kinds, with the waste water of a town, has just occurred, and little time has been given for mechanical, chemical, and bacterial actions to take place in the sewers, we have a liquid containing organic matter quite differently constituted—that is, of a different mechanical and chemical composition—from the same matter in the sewage when opportunity has been given for these various actions to take place. The sewage at first contains generally free oxygen and nitrogen in the form of nitrates and nitrites, and the proportion of organic matters in suspension is comparatively large. Such a liquid we call *fresh sewage*.

"As this fresh sewage flows along the sewers, mechanical, chemical, and bacterial forces act upon it, and the composition of its organic constituents under-

* *Vide* Report of the Sanitary Commissioner with the Government of India for 1898, page 277.

goes a distinct change. This change is practically the breaking up of the organic matter into simpler forms, and is the initial step in the process by which the organic matter is finally changed to inorganic matter. The change carried on in fresh sewage containing free oxygen is as follows:—The carbon, under bacterial influences in the presence of free oxygen, is oxidised, the nitrogen and hydrogen unite to form ammonia, and this unites with the carbon dioxide to form ammonium carbonate. Thus, until the dissolved oxygen is exhausted, the free ammonia increases, while the crude organic matter decreases. Sewage when its free oxygen has just become exhausted and its free ammonia increased to the maximum possible by the exhaustion of its oxygen, we designate as *stale sewage*.

"Sewage containing free oxygen, and for this reason comparatively free from putrefying actions, has not a particularly offensive odour, and the same can be said, though in a less degree, of stale sewage. When the oxygen is exhausted, bacterial life continues active, and chemical changes go on and continue the breaking up of the organic matter into simpler forms. But as oxygen is not present, the action by which the organic matter is still further changed is a putrefying one, and the sewage becomes very ill-smelling on account of the generation and escape of hydrogen compounds of carbon, sulphur, and phosphorus. Nitrogen is also set free in this putrefying process. The result of all these changes is to decrease the amount of carbonaceous and nitrogenous matter in the sewage. Sewage when in this state is now known, since the results of certain English experiments have been published, as *septic sewage*—not a very appropriate term, but one which we shall probably have to accept on account of its general use at the present time. This action, resulting in the change of stale sewage into septic sewage, can probably, if sufficient time is given, be continued until nearly all the organic matter in suspension is changed into soluble forms."

In most towns, therefore, it is *septic sewage* that has to be dealt with, but in the experiment, which is about to be described, the sewage must be classed as *fresh sewage*; for, as will be seen, it was delivered directly into the septic tank as soon as produced.

One of the objects of the experiment was to ascertain whether it would be possible to carry out the satisfactory disposal of sewage in the crowded quarters of a town, and thus avoid the nuisance and expense of its carriage to trenching grounds. Such sewage would in all probability consist of a large quantity of fresh sewage from the public latrine in or near the septic tank and a mass of septic sewage from the neighbouring private latrines. It was therefore originally intended, as soon as the septic tank and filters had been brought into thorough working order, to deal not only with the fresh sewage produced in the latrine, but also the septic sewage from Fort William. Considering, however, the site of the experiment—a few yards only from a public road, and a few hundred yards only to the north of the general hospital—it was thought undesirable to carry out this part of the experiment by reason of the nuisance that might possibly arise from the presence of a number of night-soil carts waiting to discharge their contents into the septic tank. It is very doubtful, however, whether the introduction of sewage, which had already reached the putrefactive or septic stage, into a tank containing similar sewage would have any real effect on the satisfactory working of the whole system.

CHAPTER II.—Structural Details.

It will have been understood that the supply of sewage for the experiment was derived from a latrine used by the native warders of the Presidency Gaol, and it was the size of this latrine that practically decided the area occupied by the septic tank. The superintendent of the gaol decided that a ten-seated latrine was required, and this was provided for in two rows of five seats each, separated from each other by a space of 3ft. in which the flushing valve for each seat was fixed, and having passages 3ft. wide in front. Each seat consisted of an ordinary closet pan at floor level, but fitted with Donaldson's patent automatic foot rests, by which the weight of the user is utilised in working the valves of the small flushing vessels in the valve chamber. Each flushing vessel was designed to contain exactly three gallons, the quantity now acknowledged to give the most effective flush; and the water was obtained from overhead tanks supplied in their turn from the Calcutta Corporation's filtered-water mains. Each pan discharged into a 6in. drain running underneath the valve chamber between the two rows of seats, and the sewage from the drain was discharged into the brick masonry tank on the top of which the latrine was constructed. In order that the sewage might be dropped into the tank with as little surface disturbance as possible, the end of the 6in. drain was formed of a vertical iron pipe with its mouth 2ft. 6in. below the normal level of the liquid in the tank; this arrangement also had the additional advantage of preventing any gases from the septic tank finding their way into the latrine and perhaps forcing the traps. The 6in. drain was ventilated at its summit and anti-syphonage pipes were provided for all traps; the ventilating pipes could also be used as a flushing pipe through which the whole of the contents of the overhead tanks could be discharged if it was ever found necessary to flush out the 6in. drain. The latrine was so close to the public road that the greatest care had to be taken in its construction so as to avoid all possibility of any nuisance.

The septic tank under the latrine was divided into two compartments—one measuring on plan 8ft. by 3ft. and known as the grit chamber, and a second, 8ft. by 15ft. The two chambers were connected by seven passages in the dividing wall, each measuring 5in. by 3in., and at a height of 3ft. from the floor, or practically at the same level as the mouth of the vertical iron inlet pipe. The object of the grit-chamber was the collection of the silt from the flushing water and the bits of brick that certain classes of natives prefer to use instead of washing water. The floor of the grit chamber was flat, whereas that of the septic tank sloped upwards towards the outlet pipe; the normal depth of liquid in the septic tank was 5ft. 3in. at the grit-chamber end, and 4ft. 6in. at the outlet end. The roof consisted of two arches carried by a central iron joist and the side walls. Following the Exeter example, the outlet from the septic tank consisted of 4in. galvanised wrought iron pipe with a slot cut in it throughout its length; there appears to be no particular advantage about this method of drawing off the liquid, and it is extremely problematical whether it does what is claimed for it, namely, to draw off the liquid evenly from the whole width of the tank. The discharging end of the pipe was fitted with an ordinary ball-cock so as to maintain a constant discharge. This was found to be a somewhat inconvenient arrangement, as it only permitted of one rate of discharge neither more nor less, and so a screw valve was designed and fitted. This did not prove satisfactory and caused much more trouble than the ball-cock, the reason being that the small quantity of matter in suspension in the effluent from the tank gradually accumulated and choked the valve; this state of affairs could not have happened with a ball-cock, because directly the rate of discharge became reduced owing to the accumulation of matter the ball drops and opens the cock more widely, and thus causes the accumulation to be flushed out by the increased discharge. The most satisfactory valve would probably be a ball-cock with the ball sliding on the arm so that it could be suitably adjusted for any desired rate of discharge.

Manholes fitted with cast iron covers were provided

in both the grit chamber and septic tank, as also sludge outlet pipes laid at floor level, so that the whole contents of the tanks might be discharged into the Calcutta sewers with the least possible delay. The height of the surface of the liquid in the tank was gauged by a plumb-bob passed through a hole in one of the manhole covers; except for this small hole, which was kept plugged as much as possible, the tanks were kept practically air and gas-tight, for no arrangements were made for drawing off the gas from the putrefying sewage, and no inconvenience has been felt. Before passing on to the filters the effluent was discharged over a triangular notch that served the double purpose of measuring and aërating it.

The filters were two in number, each measuring 13ft. by 8ft. 6in. by 4ft. 2in., and made of brick masonry; they were separated from the main tank structure by a space of 3ft. wide and running the whole length of the tank, the object of the chamber thus formed being to give room for the erection of automatic filling and discharging valves. No such valves were ever used, and the space was partially utilised for the erection of a small Scott-Moncrieff tray filter. The experiments of Professor Frank Clowes and others as to the capacity of filters filled with different materials, had not been made when these filters were designed, and they are really much too big for the quantity of effluent they had to deal with. It is generally reckoned now, as a rough approximation, that the air space, or the space available for occupation by a liquid, is one-third of the cubical contents of the filter chamber; no exact rule has been laid down on the subject, nor is such possible because of the varying character of the substances used for filtering material. In this experiment the filtering material consisted of a 3ft. depth of furnace slag in one filter and furnace-bar clinker in the other, laid over 9in. of brick *khoa;* the furnace slag varied from 1in. to ¼in., and the furnace-bar clinker from ½in. to ⅛in. diameter. Various devices were experimented with for discharging the effluent on to the filters, but no one arrangement gave better results than the other, and for the greater part of the time the effluent was discharged through two cocks straight on to the filtering material. When the filtering material near the cocks showed signs of getting clogged it was simply turned over and thoroughly exposed to the air; after a short time all traces of clogging had disappeared.

The filtrates were collected in two masonry wells or vats, measuring 4ft. 10½in. by 3ft. by 4ft. 3in., which were connected at first with the Calcutta sewers, but after a short time the filtrates were so satisfactory that the connection was stopped, and the filtrates allowed to discharge down a small masonry ladder into a low-level tank in the gaol garden. The maximum level of the water in this tank was practically the datum from which all the other levels of the installation had to be determined; it was desirable in the first place to ascertain what would be the result of the continuous discharge of partially-purified sewage throughout the year into the tank, and it was at the same time necessary that the filters should not be water-logged and thus prevent the ingress of air through the outlet valves while the filters were not in use.

There is no necessity to give a statement of actual cost of this experimental installation, as it would not serve as a guide in any way for the cost of equally efficient works in the mufassil. The latrine on the top of the septic tank is probably the best of its kind, but it had to be for reasons already given. The filters are much too big, and there is no necessity to make them water-tight. The cost of sewage disposal works on the septic-tank system is practically regulated by the rate for brick masonry, as there are no very special fittings required nor special work of any description. All that is required is a water and air-tight tank and three small filters with earthen banks, and a low-level tank into which the filtrates can be discharged. It may be possible later on to discharge the effluent from the septic tank direct into a roadside drain, provided that drain is lined with masonry, for the effluent is certainly not more offensive than the usual contents of such drains in crowded bazaars.

(*To be continued.*)

THE HYGIENE OF MUD.

The man in the street is apt to look upon mud with anything but friendly feelings, but according to the *Lancet*, there is a consolation even for the mud-besprinkled. This happy solace is to be found in a comparison between the hygienic effects of mud and its opposite condition of dustiness. Of course mud is, roughly speaking, wet dust, and dust is dry mud; but the evil effects of dust far transcend those of mud. In the dissemination of disease, mud remains comparatively innocent, but for the behaviour of dust in this respect no words can be too strong. Widely disseminated and inevitably inhaled, dust particles carry and deposit enormous quantities of disease. Its local and comparatively trifling damages, conjunctivitis, pharyngitis, and rhinitis, pale before its evil powers in carrying more formidable disorders. It has recently been shown how summer diarrhœa is wont to prevail most where there is most dust, and that dust may contain the dried sputum of phthisical patients is only too familiar to us all. These are only two of the graver diseases in the distribution and implantation of which ordinary dust plays a leading part. There are still other complaints in which the inhalation of ordinary dust is baneful, not to mention the special diseases caused entirely by special forms of dust, and our contemporary would have it borne in mind that mud has no similar evil influence. Mud is largely water. Paradoxical as it may sound mud is clean, at least as compared with dust. Moreover, the ultimate fate of mud is in the drain-pipe of the street, but dust too often ends in the windpipe of a man, if not in the alveoli even of his lungs. In future, then, let us not revile the passing Hansom, nor as we wipe from our collar the mud of London's winter streets too fully condemn it; but rather gratefully reflect that a passing inconvenience, a mere temporary disfigurement, is a small price paid for freedom from the evil possibilities of the dust of an apparently brighter day. The ideal street knows neither mud nor dust. But in a world of imperfections let us not too hastily condemn mud. Let us rather congratulate ourselves on the absence of dust.

The ceremony took place at Prescot, a short time back, of cutting the first sod of a new reservoir to be constructed there by the Liverpool Corporation for storage purposes. The land where the reservoir will be is a portion of the Knowsley estate, and it will adjoin the existing reservoir there, which is also used for storage purposes. The ceremony was performed by the Earl of Derby.

The St. Bride's Press Limited, 24, Bride-lane, Fleet-street, E.C., announce the immediate publication of a book on "The Theory of Engineering Construction," by Mr. Ernest H. Essex, A.M.I.C.E., assistant engineer and surveyor to the Leyton Urban District Council. The book will form a valuable work of reference for civil engineers and students, comprising as it does a selection of notes and formulæ on the theory of construction, arranged in the form of answers to the questions set at examinations for the election of associate members of the Institution of Civil Engineers. The price of the book is 5s. net.

THE HOUSING PROBLEM.

WOLVERHAMPTON AND ITS 2000 INSANITARY HOUSES.

Councillor R. E. W. Berrington recently delivered a lecture in the Wolverhampton Free Library Lecture Hall, on "The Housing Problem." Alderman Levi Johnson presided, and among those present were the Revs. W. T. Milligan and C. Dunkley; Councillors A. Weaver, C. P. Plant, E. White, and J. Jones; Messrs. T. G. Baker, S. M. Wright, C. Boyes, W. Knight, J. Elliot, J. Peers, H. Moreton, &c.

Alderman Johnson said that many who had attended that gathering were no doubt expecting to have a corner of the curtain lifted with respect to the report of the Housing Committee, which would shortly be submitted to the Wolverhampton Town Council; but as far as he was concerned, he had no intention of making known what that report was going to be before the proper time. He hoped to be able to place the report before the Council at the meeting in January. The subject of the housing of the working classes was one of the highest importance, and there was no one on the Housing Committee who knew more about it than Councillor Berrington.

Councillor Berrington said that as a member of the Housing Committee he was sworn to secrecy, but he could tell them that there would be something good in the report of that Committee. In Wolverhampton, the housing of the artisan class was being fairly dealt with by private enterprise, but the very poor had not been touched. No town in England had dealt with the housing of the poor, but with that of the artisan class. Wolverhampton had an immense amount of slum property, and sooner or later it would have to be dealt with. There were people living in the slums who ought not to be there, because they were getting good wages, and ought, for the benefit of their families, to live in better houses. People died three times as fast in slums as they ought to die under normal conditions. In Birmingham Dr. Hill had stated that there were 10,000 houses that were quite unfit for occupation, and he (the lecturer) had said that there were 2000 houses in Wolverhampton that were unfit for occupation. He should have no difficulty in proving what he had said. In Wolverhampton they had a population of 95,000, and there were 20,600 houses, or 28 people on every acre. In St. James's and St. Matthew's Wards there were at least 600 houses that were in an insanitary condition, but such houses were not confined to one or two particular wards, for they were dotted all over the borough. Many of the people in the slums paid 1s. 9d. or 2s. 6d. per week, and he thought that the landlords made a good thing out of the rents, for such property could be erected and be made to pay 10 per cent. In Wolverhampton there were 3000 houses with rents ranging from 1s. 9d. to 3s. 3d. They had 1695 people in receipt of out-relief in the borough, with 616 children, and 659 widows in receipt of relief, and he thought that that was a workable number to deal with. The wonder to him was how people lived in the slums, for he could not conceive how people could be good or honest among the surroundings they were in. With cheap tram-fares they might induce many people to live some distance from where they worked. If anyone wanted to spend a pleasant day, he should advise them to visit Bournville, near Birmingham, and see the artisans' dwellings there. Even close to Wolverhampton—at Wednesfield—something was being done in this direction, for in connection with the chocolate works erected there, houses were being erected for the workpeople, where they would be away from the smoke. If the slum property of Wolverhampton were got rid of the rates would be lowered. Slum properties were disease centres, and to remove them they must have the co-operation of the owners. He would rather die poor than continue to draw rents from slum property. When old houses were pulled down, and new dwellings erected, the old bricks must not be used again, for bricks breathed, and in the insanitary houses had been breathing filth for the last seventy years.

Mr. T. G. Baker, in moving a vote of thanks to Mr. Berrington, said that although the hall had not been filled to listen to Mr. Berrington's lecture, the meeting was a representative one, for they had representative working-men present, and there were also representatives of the clergy, who had been working for the better housing of the poor all their lives. In Wolverhampton they had property owners exploiting the poor in order to get 10 or 15 per cent. dividends, but yet those were the people who complained about the rates.

Councillor White seconded the motion. He said that from the first day he left college he had taken the greatest interest in the question of the housing of the poor. At one time he used to spend three nights a week and every Sunday in the East End of London, in the district at the back of Shoreditch Church, and it was there that he found his wife, who was working in a ragged school. The great difficulty he found in moral and spiritual work was the hovels in which the poor people lived. He found seven or eight persons living in a single room, and had seen a corpse laid out on the table of a room in which there were several people drunk. He determined that if ever he became a member of a Council he would make the housing question his one great point. He hoped that when the Council erected dwellings they would have the right people living in them, for the people they wanted to help were the abject poor, who could not help themselves.

The motion was carried, and Councillor Berrington replied.

Alderman Johnson, in reply to a vote of thanks to himself, said that the Housing Committee were making sacrifices of time on the question, and it was the deserving poor, and not the spendthrifts, that they wished to help.

ELECTRIC TRAMWAYS AND ASPHALT PAVEMENTS.

Various attempts have been made in Germany to devise a means whereby the destructive influence exerted by the passage of heavy electric tramcars upon asphalt pavements may be counteracted. Hitherto, says a German trade review, these endeavours have been without definite result, but much has been said lately in praise of a system which is shortly to be subjected to a practical test in Berlin. Contrary to ordinary practice, in which the tram lines are laid upon a foundation of concrete, further resting in direct contact with the superimposed asphalt, the new method consists in laying the rails upon a bed of coarse gravel and running a line of hardwood blocks along either side. Experience has taught that ordinary pavements with gravels and stone foundations in place of concrete offer the greatest resistance to the influence of electric cars. It is assumed that the gravel or stone allows the rails more play, which is advantageous in that, despite great care in their manufacture, it is impossible to ensure exact uniformity with the gauge of the cars. The new method is also relied upon to reduce the noise caused by the cars running over the lines.

Having regard to the recent arsenic scare, the Edmonton District Council has authorised its Medical Officer and Sanitary Inspector to take samples of beer whenever they have any suspicion concerning it.

THE PURIFICATION OF SEWAGE.

An interesting address on the purification of sewage was recently delivered to the Architectural Association of Ireland by Dr. Adeney.

Dr. Adeney stated that after several years of doubt and uncertainty, the purification of sewage had become generally recognised as a matter for its own micro-organisms to effect, and what the chemists and engineers had to do was to make provision for the conditions which had been discovered to be necessary to keep the micro-organisms of sewage healthily and busily engaged in exercising their true functions, that is the oxidation of the polluting matters with which they were associated, and to prevent them from becoming, what they certainly would be, if subjected to conditions unsuitable to their own healthy life processes—a danger to health. The necessary favourable conditions, and the amount of work which these micro-organisms were able to perform in the way of purifying large volumes of sewage had to a great extent been worked out by the efforts of a large army of investigators in these countries, in America, and on the Continent, and it was gratifying to be able to state that Irish workers had borne an honourable part in advancing our knowledge of this great subject. One condition was absolutely essential for these organisms, and that was an ample and constant supply of oxygen. The actual amount of oxygen required for the purification of a given volume of average town sewage after the solid matters in suspension had been removed from it, could now be determined with great accuracy by a method suggested and worked out in this country. It has been shown from investigations carried out in the laboratory during the years 1890-95 that an average town sewage, after the solids in suspension had been separated from it, required one and a-half times its volume of air to supply the volume of oxygen required by the micro-organisms of the sewage to effect the complete purification of the same. These figures have since been completely confirmed by experiments carried out on a large scale. It was not so difficult to supply large volumes of town sewage with the air required for their purification as might have been expected. The real difficulty had been, and was still, that of expense. One of the easiest ways of supplying the necessary oxygen to sewage was by diluting it with good river or sea water. Forty volumes of either contained an ample store of dissolved atmospheric oxygen to supply the organisms for the oxidation of the polluting matters in one volume of standard town sewage after the solid matters in it had been removed. Hence, when a populous city like that of Dublin is fortunately situated on a tidal river, with a strong ebb current to the open sea, its sewage is easily and satisfactorily disposed of, by first separating the solid matters it contains and then discharging the liquid portions on the ebb tide only, and as near to the mouth as possible. This statement would, no doubt, surprise many in Dublin, accustomed as they were to the foul state of the river Liffey, but this was because the sewage had been from time immemorial discharged into it in ignorance of all principles. Were the solids first separated and the liquid portions discharged only on the ebb tide, and near to the mouth of the estuary, it would do no more harm than had the Rathmines and Pembroke sewage, which had now been discharged into the estuary for the last twenty years. When towns are less fortunately situated the problem of the purification of their sewage became much more complicated. In addition to having to furnish the large volumes of air a large army of organisms had to be cultivated and concentrated in a small area. Both these conditions were most efficiently satisfied by filtration through suitable porous land or through artificial filter beds. After the filter had been in use for a short time, organisms commenced to grow upon the surfaces of the material forming the filter; they then multiplied with enormous rapidity and soon covered them with semi-transparent masses of organisms which oxidised, with astonishing rapidity, the organic matter in the sewage, as it passed over them in thin film-like streams, the oxygen being supplied from the air in the insterstices of the filter. After a time this supply of oxygen became exhausted, and the passage of the sewage through the filter was stopped to allow the air in the interstices to be renewed. The filter might then be employed again, and so on for a long time. Besides being the most efficient means of purification, filtration is the quickest, effecting the purification in the course of a few hours. The size of the filter beds required for the purification of the liquid sewage of a given town could be easily calculated, when the volume of air required for its oxidation had been ascertained by the method above referred to, since the organisms always required like volumes of air for the purification of like volumes of similar sewage, and since the total volume of air in a filter might be taken as equal to one-third its own volume. It had been calculated from laboratory experiments that three acres of filtering bed 3ft. thick could purify 1,000,000 gallons of liquid sewage, supposing the filter to be filled three times every twenty-four hours. These calculations had recently been confirmed by Mr. Mansergh, President of the Institution of Civil Engineers, London, in a report to the Sheffield Corporation. The one great objection to filtration was that of cost. It was to get over this difficulty that Mr. Kaye Parry and the speaker had suggested the addition of small quantities of nitre, which could furnish oxygen in a condensed form to the organisms as a substitute for nitration. There was a second important question in the sewage problem, that was the separation and disposal of the solids of sewage, and this had proved in the past quite as difficult as that of the liquid portions of the sewage; but with our present knowledge of the chemical and biological principles underlying this part of the problem there need not be any doubt that all difficulty in its practical solution would soon be overcome. By means of the septic tank it seemed possible to satisfactorily dispose of about 50 per cent. of the solids. The septic tank was simply an open cesspit, on the surface of which the solids were allowed to accumulate until they formed thick crusts completely covering the surface, and gradually rising above it for several inches. In this condition the solids became drained and freely exposed to the air, and were then rapidly oxidised by their own organisms. But the septic tank only disposed of 50 per cent. of the solids. Mr. Kaye Parry and the speaker had, however, shown that the solids could be satisfactorily disposed of in accordance with bacterio-chemical principles by precipitating them by means of certain compounds of manganese. The solids were then separated, and at the same time were mixed with certain oxides of manganese, which contained oxygen in a combined or, as we may term it, in a condensed form that could be utilised by the organisms. When the separated solids and oxides of manganese were stored in heaps the solids did not become offensive, but underwent slow oxidation until they were completely oxidised and could be safely used as valuable manure. Dr. Adeney said, in conclusion, that he trusted he had said enough to show that the disposal and purification of sewage on a large scale was from beginning to end a work for its own micro-organisms to perform, and that the conditions most favourable for keeping them healthy and constantly employed, and all maximum amount of work they could do, are all factors in the great problem of sewage purification, which were gradually becoming more and more clearly visible and attainable as the reports of each new effort to bring the organisms into operation on a large scale were published.

National Health Society.

OFFICIAL TRANSACTIONS.

Six lectures on "Sick Nursing" will be delivered by Sister Katharine (Lecturer to the National Health Society, and late of St. Bartholomew's Hospital), in the Committee-room, 53, Berners-street, W., on Thursday, January 24th, 1901, and five following Thursdays, commencing at 3.30 p.m. The fee for the course is 10s. 6d. Tickets and syllabus to be obtained on application to the Secretary at the office, 53, Berners-street.

The following is the syllabus of six lectures on "First Aid to the Injured and Sick," to be delivered by J. Cantlie, M.A., M.B., F.R.C.S., in the Committee-room, 53, Berners-street, W., commencing Monday, January 28th, 1901, at 3 p.m.

Monday, January 28th.—Lecture I.—First Aid to the Injured: what it means. The structure and function of the human body, including a brief description of the bones, joints, and muscles. Dislocations. Sprains and strains. Practice: The triangular bandage, and how to use it.

Monday, February 4th.—Lecture II.—Hæmorrhage: Arterial, venous, and capillary. The circulation of the blood and the position of the main arteries. How to treat arterial bleeding in various parts of the body. Bleeding of varicose veins, from the nose, the lungs, and the stomach. Practice: Digital compression of arteries, and the application of tourniquets.

Monday, February 11th.—Lecture III.—Fractures: Causes, varieties, and signs of fracture. Treatment of wounds. Practice: Application of temporary splints.

Monday, February 18th.—Lecture IV.—Insensibility: its various causes, and how to tell them. The nervous system. How to aid the fainting, those suffering from epileptic and apoplectic fits, from sunstroke, shock, injuries to the brain and spine, stunning, hysterics, intoxication, and opium poisoning. Practice: Application of the roller bandage.

Monday, February 25th.—Lecture V.—General Ailments: Foreign bodies in the eye, ear, and nose. Bites and stings. Hydrophobia. Burns and scalds. What to do when the dress catches fire. Frost bite. Organs of respiration. Choking. Hanging. Suffocation. Drowning. The restoration of life in the apparently drowned or otherwise suffocated. Practice: How to perform artificial respiration.

Monday, March 4th.—Lecture VI.—Poisons: their effect and treatment. Organs of digestion. Carriage of injured or sick persons. Practice: General recapitulation.

Each lecture will last about an hour, and will be followed by half an hour's practical work, in which those attending the lectures will have opportunity of taking part. Tickets and syllabus of the lectures may be obtained at the office of the National Health Society, 53, Berners-street, Oxford-street, W. Fee for the course, 10s. 6d.

Sanitary Inspectors' Associations.

Midland Branch.

Last Saturday the members of the Midland Sanitary Inspectors' Association visited Wednesbury for the purpose of inspecting the Corporation Sewerage Works at Bescot. In the course of the afternoon they were received in the Council Chamber by the Mayor (Councillor Knowles), by whom they were afterwards entertained to tea.

AN IMPROVED FILTER CLOTH.

An improved filter cloth for sewage sludge, yeast, wine, and other presses has been designed and the patent applied for by Mr. W. J. Bosley, superintendent of the sewage and house refuse disposal works of Southampton, and others. This invention is designed to meet the requirements of a cheap and effective cloth for filter presses. Much trouble has previously been experienced in dressing filter presses, owing to the bad and inferior system of jointing in the centre, and which resulted in bad filtration, blockages of the water channels, and oftentimes a breakage of press plates.

On the improved method the centre holes are cut true to size, according to the size press in use, and are jointed in the centre by a strong webbing, which obviates the whole of the difficulties above mentioned, the result being that the cloths lie perfectly flat on the surface of the plate. The centre hole offers no obstruction to the matter forced into the filter presses, and the space allowed by makers of filter presses between each chamber remains perfectly free.

No leakage can possibly take place where the cloths are stitched, which has hitherto been a source of trouble, as the whole are double-stitched by a specially designed machine. Those now in use prove their efficiency in filtration, as the plates remain perfectly clean and there are no breakages. The cloths last longer than the ordinary made cloth, yet cost no more, owing to their being manufactured by machine, which has dispensed with the tedious hand work.

A forty-eight chamber press can be dressed in one hour. These cloths have met the desired requirements by the manufacturers of sludge and other presses, and also have the approval of the leading sanitary engineers of the day. In connection with these cloths a simple, economical, and effective clip is designed to hold the cloths in position, which makes the whole arrangement one of simplicity and cheapness, combined with durability and efficiency.

WELSH WATER AND THE TEETH.

Birmingham, according to a statement made at the forty-first annual meeting of the Dental Hospital, is likely to want a great many dentists shortly. Emphasising the necessity of a new hospital, one of the speakers said that since Glasgow had had its water from Loch Katrine dental caries and rickets had largely increased in the city. In South Africa the same effect of using soft water had been observed among the natives. He had inquired as to the percentage of recruits for the army rejected on account of bad teeth and found that of the recruits from Birmingham it was very small indeed. This was attributed to the hardness of the water drunk in Birmingham. When they got the soft Welsh water they might expect to have a large increase of dental caries, and it was important that they should prepare for this by having a better-equipped hospital.

The Lord Mayor thought these remarks constituted a very strong argument in favour of the new hospital, though he felt rather dismayed at such a statement because the special quality for which the Welsh water was recommened was its softness.

The Ven. Archdeacon of London (Dr. Sinclair) has consented to preside at the annual dinner of the Sanitary Inspectors' Association, to be held at the Holborn Restaurant on February 2nd, 1901.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

I ADVERTED a few weeks ago to the absence in bye-laws as to new buildings made under the Public Health Acts of any clauses regulating the materials to be used for the internal plastering of houses. The omission in the Building Bye-laws and powerlessness of Local Authorities to restrain the use of improper materials has been discovered by that *honest* individual—the speculative builder—and as a consequence he finds it profitable to use garden loam, in lieu of sand and hair, for his coarse stuff, and as a consequence the ceilings of such houses almost invariably fall down within two years after construction, to the serious loss of both the new owner and tenant.

THE builder knows full well when using such material that it is a dishonest and fraudulent practice, but he has no qualms of conscience except when the arm of the law, instituted by Sanitary Authorities, threatens him. He is ever protesting against what he terms the interference with the liberty of the subject caused by the enforcement of bye-laws and as to the injustice of a man not being able to do as he likes with his own property—a species of claptrap which is found to influence the weak-kneed and less intelligent class which is sometimes found among Councillors.

IT would, however, appear that Sanitary Authorities are not justified in leaving any discrimination to, or trusting to the rectitude of, the speculative builder; and the Local Government Board, who until quite recently were adverse to the inclusion of any clause in building bye-laws regulating the materials to be used for the plastering of houses, have now withdrawn their objections, and approve bye-laws as to new buildings containing clauses as to plastering made under Sec. 157 of the Act of 1875, and among towns which have obtained such a clause I notice that Hove has obtained such.

THE clause in the Hove bye-laws is, however, it appears to me, not nearly so satisfactory or conducive to sound work, and also to facility of proper interpretation, as that in the bye-laws of the London County Council, which prescribes that "All laths used for plastering shall be sound laths free from sap, &c. Plastering or coarse stuff shall be composed of lime and sand in the proportion of 1 of lime to 3 of sand, mixed with water and hair. . . . . The lime to be used must be freshly-burnt lime. The sand must be clean sharp sand, free from loam or earthy matter. The hair to be used must be good and sound, and free from grease or dirt; 1 lb. of hair to be used to every three cubic feet of coarse stuff," &c. Such a clause as the above obviates all disputes, and I would advise those of my readers who contemplate having a similar clause introduced into their bye-laws to obtain it in full, which can be found in Banister Fletcher's "London Building Act, 1894," price 6s., which is a text-book for architects, surveyors, builders, &c.

IT will be doubtless of some interest to my readers to learn that the Local Government Board now also approve bye-laws regulating the construction of drains to existing or old houses, and that a number of Local Authorities have adopted such bye-laws, and the same are already in force. Such bye-laws also provide for separate drains for conveying sewage and storm water, and enable the Sanitary Authority to enforce inspection chambers with proper covers at each point in a drain where a change of inclination or direction is necessary. It has long been doubtful in the eyes of our legal friends whether Sanitary Authorities could enforce separate drainage and also whether inspection chambers could be enforced on drains. Their doubts may, however, be now set at rest, and Municipal Surveyors may, by their Authorities adopting such bye-laws, ensure more efficient work than would otherwise be possible.

MUNICIPAL Surveyors and Architects are frequently required to execute schemes for lighting buildings by gas, and are required to exercise the same control over the fittings as over other branches of building. It is essential in fitting a building with gas pipes that an equal distribution of gas be provided, so that when fully lighted the pressure is equal at all points on the same level. There happens to be few hand-books which are of much service in guiding the architect in such work, and I have therefore pleasure in drawing attention to the excellent little hand-book, viz.:—Stott's "Architects' and Surveyors' Hand-book of Gas Fitting," price 6d., published by Messrs. James Stott and Co., the well-known lighting and heating engineers, of 34, Queen Victoria-street, E.C. There are no abstruse formulæ to be worked out by the reader, for these have been done for him, and tables and tests, which are readable at a glance, are furnished, and a form of specification is given. The little book will be found very helpful.

I SUPPOSE that five years ago Acetylene as an illuminant was unknown in this country. At the present time, however, it is used for a numerous variety of purposes—from the lighting of small towns, from one common generating station, and for isolated buildings and railway stations down to portable lamps for contractors—also for table use, and for bicycles which generate their own gas. The light given off is bright and steady. It does not consume so much oxygen as coal gas, nor vitiate the atmosphere of a room to the extent that coal gas does, and it is cheaper, light for light, than coal gas. The disadvantages, until comparatively recently, attendant upon its use were the danger of explosion from the storage of calcium carbide, from which it is manufactured, and the cost of manufacture of the latter material. These disadvantages have now been considerably reduced by the construction of factories in Great Britain for making the compound, and by the introduction of numerous forms of apparatus for the manufacture of the gas from carbide of calcium in a portable, safe, and economical method, by new companies which have lately come into existence, such as the "Phos" Acetylene Gas Syndicate, Limited, 1A, Shacklewell-lane, Hackney, N.E., and Worsnop and Co., Limited, Carlton Lamp Works, Halifax, who manufacture self-contained lamps; the Forbes Acetylene Gas Company, Regent-street, Kensal Green, London, W.; Turr's Acetylene Gas Syndicate, Limited, Orchard-street, Great Smith-street, Westminster, S.W.; Thorn and Hoddle Acetylene Company, Limited, 1, Tothill-street, Westminster, S.W.; and numerous others who manufacture plant for installations for hall, homestead, hamlet, and factory, whilst the Acetylene Illuminating Company, Limited, of 3, Victoria-street, Westminster, S.W., have established a large factory at the Falls of Foyers, in Scotland, for the manufacture and sale of carbide of calcium.

THOSE of my readers who may be called on to advise as to the lighting of villages or isolated institutions or buildings would do well to inform themselves of the system, as it will without doubt be applicable in such cases, and its extension in a variety of ways may be looked for. The little town of Portsoy, in Banffshire, was the first in the kingdom to adopt acetylene as an illuminant over two years ago, and the chairman of the Local Council reports, after two years' working, that there had been no hitch nor trouble nor disappointment with the plant (which was constructed by the Manchester Acetylene Gas Company, Limited, Manchester), and that Portsoy is the best lighted town in Scotland of

its size. There are now many other villages in the kingdom which have adopted the light, and I doubt not that there will be a rapid extension of the system generally, as the cost of an installation is much less than that of a coal-gas plant.

I NOTICE in a return recently obtained relating to refuse destructors that in the six important towns of Bradford, Brighton, Birmingham, Leeds, Manchester, and Salford, there is provided on an average one cell to every 9000 inhabitants. Bradford has the largest number of cells for its population, having one to 6740 inhabitants, and Brighton has the least, viz., one to 10,220 inhabitants. The average capacity of these destructor cells is 5 tons per day, and the average number of working days in a year is 300. The Horsfall destructor continues to be, I notice, widely adopted, and to give excellent results. Those of my readers who require a good book on this subject should procure Maxwell's "Removal and Disposal of Town Refuse," price 15s., which is a veritable mine of information about destructors and refuse collection and removal generally, and is, I believe, the only impartially written book on refuse destructors to be obtained.

IT is singular that Local Authorities and their Engineers should so commonly fall into the error of honestly believing that the heat generated from the burning of house refuse in dust destructors is of such power as to be able to generate sufficient steam for driving the electric lighting plant for their towns. Such a common delusion should have been exploded long ago, but it still survives—in the specious arguments of interested patentees. The calorific value of house refuse is generally very small, and varies in each town. The refuse of towns adjacent to coalfields, or of a district like Shoreditch, in London, which is the centre of the cabinet-making industry, may be of commercial value in a destructor, but in a large number of cases its value is practically worthless, as many Authorities have found to their cost, and it is time that municipal engineers candidly advised their Local Authorities of the true position.

THE mistaken notions on this subject are to be traced to a statement made by Professor Forbes, in his Cantor lectures, before the Society of Arts in 1892, who said that, "*If* that refuse (at Paddington) were *properly burned*, and *if it were used in the most economical way*, it would be found that, assuming the proportion of lighting required for such a population to be, as has been very generally assumed, one lamp per head, the amount of refuse provided by any population is almost exactly as much as is required to supply the illumination by means of the electric light to that same population."

IN actual practice the conditions suggested by the Professor are unattainable; refuse is not burned under the perfect plans intimated, and the theoretical man, has, it is seen, been the cause of perpetuating the *ignis fatuus*. It may be remembered that between twenty and thirty years ago, when sewage disposal works were first being constructed in this country, that chemists prophesied from a similar theoretical standpoint that sewage could be treated at a profit to the community, and this was provable, it was urged, by the quantity of phosphates which were known to be present in all sewage, and which were to be abstracted, utilised, and sold at prices ranging from £3 to £12 per ton. Experiment has shown that all this was but an idle dream. But the fallacy was believed for nearly twenty years. Will the fallacy as to the supposed high calorific value of house refuse obtain credence for a similar period? SENEX.

PERSONAL.

MR. A. HUDSON has been appointed Clerk of Works for Guildford.

MR. R. H. HERRING has been appointed Inspector of Nuisances for High Wycombe.

DR. STEWART has been unanimously elected Medical Officer for Bovey and Islington.

MR. THOMAS F. BROWN has been appointed Sanitary Inspector for the burgh of Kilwinning.

THE Ripley Urban District Council has accepted the resignation of Mr. R. Argile, Surveyor to the Council.

DR. BROWN MOIR, of Stranraer, has been unanimously appointed Medical Officer for the Clenock Joint Hospital Committee for the ensuing year.

DR. THOMAS J. FOX, who was recently in Ballinalee, County Longford, has been elected Medical Officer for the Milltownpass Dispensary, under the Mullingar Guardians.

DR. W. BEAUMONT, Medical Officer of Health for East Ham, is to receive an increase of £50 per annum because of his extra duties. The present salary of the Medical Officer is £150 per annum and £50 for hospital duties.

DR. JOHN MCKENZIE, L.R.C.P., and L.R.C.S., Royal College of Surgeons, Dublin, has been appointed Medical Officer to the Sunderland Medical Association which has just been formed in the town by the local friendly societies.

THE Bridgnorth Rural District Council has decided to increase the salary of Mr. R. E. Hughes, Sanitary Inspector, £20 per annum, subject to the sanction of the Local Government Board and on the condition that he keeps a horse and trap for his own use.

LAW CASES.

Infringement of the Public Health Act.

AT the Gravesend Police-court, last week, Henry Parry, the master of the steamship Monterey, was summoned by the Corporation of London, as the Port Sanitary Authority, for an infringement of the Bye-laws made under the Public Health (London) Act, 1891, in failing to report to the Medical Officer of Health on his arrival at Gravesend, a case of dangerous infectious disease, namely, typhoid or enteric fever.

Mr. LEWIS NOAD represented the owners, Messrs. Elder, Dempster, and Co., of Liverpool; and Mr. T. G. VICKERY, the Assistant City Solicitor, appeared to prosecute on behalf of the Corporation.

Mr. VICKERY stated that the vessel arrived at Gravesend on December 7th, and was visited by the Medical Officer of Health in conjunction with officers of her Majesty's Customs. In reply to the question whether all were well on board, the master stated "all well," and subsequently signed a declaration to this effect, and further that there had been no case of sickness during the voyage. On the following day it was found that the fourth engineer had been taken ill with typhoid fever on November 14th, and had been under treatment by the surgeon of the vessel since that date, with the full knowledge of the master, who had entered the fact in his official log, and had also reported it at Havre. The Medical Officer of Health thereupon removed the patient to the hospital and disinfected the vessel. These facts were not disputed by the defence, and Mr. NOAD, on behalf of the master, pleaded guilty, and stated the circumstances in which the offence was committed.

The Bench imposed a penalty of 40s. with costs.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

JANUARY 4, 1901.

CAMP AND BARRACKS SANITATION.

AMONG other important matters affecting the welfare of the Army which will have to be considered when the "New Broom" is called into operation is the question of a more efficient system of sanitation for camps and barracks. Many of the latter leave much to be desired in this respect, while the former still rejoice in methods which are altogether primitive and effete. The sanitary needs of armies in time of war have been forcibly brought home to us in South Africa, where, despite precautions, the number of deaths from enteric have been appalling; but while much is pardonable during the exercise of war, when the energies of the staff officers are tried to the utmost in other directions, there is no excuse whatever for the neglect of sanitary precautions in times of peace. Unfortunately evidence is not wanting that such neglect exists, and its influence upon the health of the Army as a whole is much more serious than appears upon the surface. In the ordinary course, where civilians and Medical Officers of Health are concerned, we are kept well posted by means of periodical reports; but, strange to relate, statistics regarding the Army, bearing directly upon sanitary matters, never find their way into the office. We are well aware that "Crown" property does not come under the jurisdiction of the Civil Authorities, but surely that is no reason why the latter should be kept in the dark. On the contrary, the fullest information should be given them, for the insanitary condition existing in barracks or camps constitutes a direct menace to the neighbourhood in which these institutions are located. An instance of the crude material of which Army sanitarians are made is furnished by a recent letter by a regimental officer to the *Times*. This correspondent suggests covered receptacles or a trench 4ft. deep for camp latrines! As every student of sanitary science knows, this depth affords exactly the *nidus* most calculated to prolong the life of pathogenic microbes, to whom light and air penetrating a shallow trench is fatal. This is only a small point, but it serves to illustrate the fallacy of Aldershot training in these matters. At the same time we must recognise the spirit which prompts a regimental officer to exercise any interest whatever in the sanitary regulations of camps. There is altogether too much indifference to the subject in Army circles, and if Lord Roberts will take this matter in hand with his accustomed far-sighted thoroughness, its effect on the rank and file of the Army will be bound to make itself felt in increased physical efficiency and general well-being.

Social Science Progress.

THE writers in the newspapers have this week been revelling in retrospects of the past century, yet very few have even noticed the greatest and most real advances which it witnessed. Political history has been reviewed, the wars—great and small—have been recounted; the triumphs of steam on land and sea; the discovery and development of electricity—all these and many other things have been set forth, but very little reference have we seen to the immense changes which have come into the lives of the people as the result of the labours and teaching of Southwood Smith and Edwin Chadwick, and the noble band of sanitarians who have followed in their wake. It is to the work done by these that we owe the improved condition of our cities and towns. If the country had been unmindful of the truths they taught, and there had continued the utter disregard of the elementary laws of health so prevalent in the early days of the century, existence would have been impossible in the congested masses which are the feature of the

national life to-day. We rejoice, with every true patriot, in the growth and expansion of our glorious empire; but we are even more deeply thankful for the fact that the advances made in social science have stamped out the pest-houses and fever-breeding dens of our forefathers; that the improved surroundings due to the same cause have added many years to the lives even of the poorest. These are the bloodless victories of the century, and, to our mind, of greater importance to the commonwealth than anything else.

A Case for Inquiry.

Some trenchant criticisms are offered in last week's *Syren* on a case mentioned in the report of Dr. Collingridge, Medical Officer of the Port of London Sanitary Authority. It appears that on May 5th the Authorities in London received information from Stalybridge of a fatal case there. The patient had travelled from Moscow to Stalybridge *viâ* Flushing and Queenborough. The eruption of small-pox had broken out before he left Moscow. How was it then he was passed at the landing-place in this country? Queenborough is within the jurisdiction of the Port of London Sanitary Authority, so this is evidently the body responsible for allowing a disease-stricken patient to travel from the Medway right through the heart of England to a populous centre of Lancashire. Of excuse for, says our contemporary, or an explanation of, this fearful neglect, we find no trace in the report before us. Why is this? What attention has been given to the matter by the Port Sanitary Committee? Any, or none? We know that the staff is too small, and have said so time and time again; the Committee admit the fact on page 11 of the book before us; they have admitted it since 1883, seventeen years ago. Why, then, have they taken no steps to increase the number of inspectors? We have never encountered a graver dereliction of duty, and we hope such steps will be taken in Parliament as shall either end or mend a system which permits a disease-reeking patient to be sent from one end of England to another, exuding contagion on every mile of his journey. Small-pox checking at Queenborough may not be so likely to appeal to the public as plague hunts at Gravesend, but it is nevertheless necessary. The fact that it is possible to even land a small-pox patient from a foreign vessel is not likely to increase confidence in our Port Authorities. But it passes our comprehension that anyone should have been allowed to transport such a person from one end of the country to the other.

The Leeds Mystery.

The ways of some municipalities are strange. For many months —we had almost written years— a Committee of the Leeds City Council has been seeking for a solution to the problem of how best to dispose of its sewage. Experiments on a most extensive scale have been carried out, and advantage has been taken of the very latest investigations and suggestions of the leading chemists and sanitary engineers of the day. The industries of the city and conditions of life introduce special elements into the sewage, but it has been found that these could all be treated successfully by bacterial methods. In fact, the reports issued by the Committee seemed to indicate that there had been discovered a combination which would meet every requirement set forth in the instructions given to it as a guide for its investigations. Such, however, does not appear to be the opinion of the City Council. Among the municipal Bills deposited for next Session we find one promoted by Leeds for dealing with its sewage. But in it the results of the Committee's work are entirely disregarded. Instead of treating it, as was possible, near at home, an expensive main drain, twelve miles long, is to be laid down, and the sewage conveyed to an immense farm, some 1890 acres in extent, for treatment. The estimated cost is £650,000, but more probably will it be three-quarters of a million. Surely there is something in all this calling for explanation. That the cost of any scheme for such a city must be considerable we willingly admit, but we do contend that modern science has made it possible to do without this profligate purchase of land and laborious tunnelling. On one-tenth of the space a thoroughly efficient scientific system could have been established. We have always given Yorkshiremen credit for being progressive in their municipal life, but when they seriously propose a scheme on the lines accepted forty years ago, and which are discarded by the engineers of to-day, it is time to review our belief in their longheadedness and wisdom. The whole thing is a mystery, and we are tempted to ask whether the farm was purchased before the Committee began its inquiries, or did it come into the hands of the Council through the friendly interposition of interested parties. But perhaps somebody will explain.

Helping the Red Cross.

One of the news agencies gives an interesting account of a novel appeal which has been made this week throughout America on behalf of the Red Cross Society of that country. It would appear that the officers of the society have recently been engaged in collecting messages of appropriate nature from notable people all over the world. Official sanction has been given to the enterprise by the State Department, which has lent all the assistance in its power to the society. The result has been a wonderful collection of documents, in which Kings and Queens, Princes and Presidents, and the foremost men and women of the present day, express their ideas on the dying of the old century and the dawning of the new. All over the United States it is the custom to watch the new year in. The Red Cross Society, therefore, conceived the notion of getting together this collection of messages, and selling a copy of them to every party which was following the universal custom, whether at a watch-night service, a private or public dinner party, a dance, a private house, or a club. Thousands of copies were made, and the services of all the express companies in America enlisted for their

distribution. The charge for a copy was 25 dollars for each party. They were delivered everywhere at eight o'clock on the night of December 31st, on the understanding that the messages were not to be read until midnight had struck. The original documents will be bound in a volume which will be deposited in the Congressional Library at Washington as a unique and valuable record of the occasion.

London's Vital Statistics.

With the close of the year was issued the report of Dr. Shirley Murphy on the health of the administrative County of London in 1899. This report is no mere copy of its predecessors, with just the figures corrected. It is an exhaustive analysis of the condition of the entire metropolis, and contains much valuable material worthy the study of all interested in municipal life in general, and that of London in particular. In a future issue we hope to deal more fully with its contents, but at present we must be content to refer to that portion giving the vital statistics. Dr. Murphy estimates the population of the county in the middle of 1899 at 4,568,689. In the year under review there were 41,853 marriages, giving an annual rate of 18·4 per 1000. The number of births registered was 133,585, giving an annual rate of 29·3 per 1000, which is the lowest birth-rate on record in London. During the year the eastern group of districts had the highest birth-rate (36·2) and the western the lowest (24·6), the northern, central, and southern groups having birth-rates of 27·2, 28·6, and 30·0 per 1000 living respectively. As in the preceding year the district having the highest birth-rate was St. Luke (44·4), and the district having the lowest birth-rate was St. Martin-in-the-Fields (12·2). The number of deaths was 87,819, giving an annual rate of 19·3 per 1000. All the eastern districts and all the central districts, with the exception of St. Martin-in-the-Fields, had in the year 1899 death-rates above the average of London. The district of St. Luke had the highest death-rate (30·7) and Hampstead the lowest (13·4). The deaths of infants under one year of age was 22,209, being in the proportion of 166 per 1000 births. During the year 1899 the eastern group of districts had the highest infant mortality (179), the northern the lowest (154), the infant mortality of the southern, central, and western groups being 164, 168, and 173 respectively. Of the districts, Holborn had the highest (226) and Stoke Newington the lowest infant mortality (103).

The City of the Future.

The ubiquitous interviewer was in strong evidence in Tuesday morning's papers, and men of all creeds and classes were enabled to give their views on the work done in the past century, as well as the tasks awaiting accomplishment in the present. The idealist was given full play for the exercise of his faculty. In this respect, Mr. Robert Donald, who has done much to awaken an interest in municipal affairs, sets forth in the *Daily News* his belief of what will be the condition of the city of the future. In reply to a query as to whether overcrowding will exist in the cities of the new century, he gives an emphatic "No." "Before the new century has run its course," he continues, "the conditions of to-day will be regarded as belonging to the horrors of the dark ages. The herding of the sexes in one-roomed dwellings will be to them a thing unspeakable. The death of one-fourth of the children in the poor parts of London before they are a year old will appear to them as barbarous. The city of the new century, spread out over a wide area, with plenty of light and air for all, will contain no slums. Disease will be reduced to a minimum; the unfit will disappear, as medical science will check physical degeneracy and strengthen the weaklings." Asked, "Will the towns of the new century, then, have their staff of municipal doctors?" he replied, "Certainly. We have now Sanitary Inspectors—a few, at least—whose duty it is to visit houses even when not invited. They look after the sanitary fittings, the dust-bins, and such like. The municipal doctors in the future will, in the same way, have sections of the city under their charge to look after the health of the people. The citizens of the future will be surprised to know that doctors were once paid for their services by private people, and not engaged by the community. They will also think it funny that doctors were only sent for after people were ill, or when disease had broken out. It will be the business of the new-century Medical Officer to visit people when he is not invited, to do his best to keep those under his charge from falling ill. He can draw from the municipal dispensary whatever he wants, and send people for change of air to the municipal convalescent homes at Margate or Brighton. The health of the individual will become a matter of communal concern." A few years ago, when Edward Bellamy said much the same thing, it was denounced as foolishness, and merely visionary. Matters have certainly advanced since then, but we are bound to confess that such a culmination as is indicated by Mr. Donald is by no means within the region of practical politics.

Bacteriological Research at the Cape.

Dr. Alexander Edington, Director of the Colonial Bacteriological Institute, Cape Colony, who is on a visit to this country, has recently furnished some interesting reports on the work which the Institute has achieved during the last few years. The Institute is supported solely by the Colonial Governments, though it has also received some aid from the Orange Free State and the Transvaal. It has done much good work in investigating the diseases to which South Africa is specially subject, both in man and in animals. The disease which has attracted most attention is horse-sickness, for the ravages of this disease have been terrible. In Cape Colony, for example, during the last outbreak 40,000 horses died in three months; and in Rhodesia and the low-lying parts of the Transvaal, where it appears to be endemic,

and of annual recurrence—its appearance being usually coincident with the malarial season in man—it is so severe that the annual mortality among horses and mules is over 90 per cent. The investigations of the Institute — the results of which we have not space at present to recapitulate in detail—have led to the adoption of certain methods of inoculation, which it is believed will in large measure remove the danger from these terrible ravages from which the Colonies have suffered in past years. It is of interest to note that during the war, though the horses of the British army passed through the affected areas, scarcely any horse-sickness occurred, which is attributed to the fact that it is connected with moist meteorological conditions, and that for some years South Africa has passed through an exceptional cycle of drought. The Institute has also conducted researches during the last ten years with hydrophobia—which first appeared in Cape Colony in 1893—and various diseases incident to cattle, with regard to all of which inoculation has proved very successful. Speaking on the subject of enteric fever, which has been such a scourge to our troops during the war, Dr. Edington stated that it was in nowise a result of the war, but was endemic to South Africa. It had been a scourge for years, and the troops marching through districts in which it lurked were seized by it. Horse sickness in animals and malarial fever in man had, he stated, constituted the great foes to the advance of civilisation in South Africa; but through the progress of preventive medicine it was hoped that the valuable hinterland would soon be rendered habitable for man and beast. The resources of the Bacteriological Institute are at present limited, but it is hoped that the Imperial Government may see its way, in connection with the settlement of South Africa, to take it over and equip it in a first-class manner, so as to increase its sphere of usefulness, and facilitate its investigations into the means of preventing disease both among the white and the black populations. The value of such an agency in promoting the civilisation of the vast territories to be brought under British rule can hardly be over-estimated.

A Tragic Experiment.

The Philadelphia *Medical Record* contains a report of certain experiments conducted by a board of surgeons of the United States army into the transmissibility of yellow fever by means of the mosquito. That mischievous insect has already been convicted of the responsibility for the transmission of malaria to the human race, and the prevalence of yellow fever among the American soldiers in Cuba led the medical authorities at Washington to suspect his responsibility for that disease also, and they accordingly appointed this Commission of investigation. Several of the doctors suffered themselves to be bitten by mosquitoes which had previously been in contact with yellow-fever patients. In one case the daring experiment was attended by fatal results. Dr. Jesse W. Lazear—after one attempt which was followed by no appreciable effects—while visiting a yellow-fever hospital on 18th September, permitted himself to be bitten by a mosquito on the back of the hand. Five days later he had a chill, after three more days jaundice appeared, and on 25th September this heroic martyr to science died of yellow fever. Dr. James Carrol, another member of the board, and a civilian volunteer, had similar experiences, though happily unattended with fatal results. It was considered to have been proved that the disease was contracted not from patients, but from the mosquito bite. From these and other cases the Board have arrived at the conclusion that "the mosquito serves as the intermediate host for the parasite of yellow fever, and it is highly probable that the disease is only propagated through the bite of this insect." This result, which is quite in line with the conclusions regarding the connection of the mosquito with malarial fever, is an extremely important one to have established, but it is sad to think that it should have been reached through the sacrifice of a valuable life.

When Doctors Differ.

A peculiar case occurred at the Sheriff Court of Linlithgow last week, which furnished a remarkable illustration of the old adage, "When doctors differ," and at the same time revealed what appears to be a defect in the Food and Drugs Acts. A dairyman was charged with selling milk from which there had been removed at least 41 per cent. of the natural fat, the analysis showing this deficiency being that of Dr. Macadam, Public Analyst for the County of Linlithgow. But Dr. Hunter, Public Analyst for the County of Midlothian, who was called as a witness for the defence, submitted a totally different analysis made by him of one of the parts of the milk sold to the Inspector. He stated that the milk contained more fat than would meet the highest standard employed by Public Analysts, and he was distinctly of opinion that the statement that "it had been deprived of at least 41 per cent. of natural fat" was absolutely without foundation. The defender's solicitor, in asking for a verdict, referred to the question of expenses, which was a serious one. While it was incompetent, he said, for his lordship to award expenses to the defendant, he thought it right to bring under his notice that the person accused and innocent could only vindicate his innocence and clear his reputation at a cost of from £15 to £20; and he submitted that it was nothing short of scandalous that any dairyman should be involved in such expense without having any relief therefrom in the event of his being successful. The Sheriff, in giving judgment, said it was impossible for him to convict. Clearly a mistake had been made somewhere. Were he to give a verdict of not guilty, it would be tantamount to finding that Dr. Macadam had made a mistake, and a verdict of guilty would be equivalent to holding that Dr. Hunter had made a mistake. As for the question of the expense, he threw out the suggestion that it would be fitting that the Local Authority should bear the expense,

and he was certain that the ratepayers would approve of such a course. We do not know whether such a course would be strictly legal, as there are very strict limitations on the expenditure of public moneys, but there is no doubt that it would be in accordance with equity.

Sewage Disposal in Glasgow.

The Corporation of Glasgow has decided definitely against the adoption of bacterial methods of treatment of the city sewage. At a recent meeting the City Engineer submitted an elaborate report, with figures showing the estimated cost, both capital and annual, the conclusion being that the cost made the bacterial methods prohibitive. Consequently it was resolved that the system of chemical precipitation, which has been in operation at Dalmarnock for a good many years with much acceptance and success, should be adhered to in the new and larger works now in progress at Dalmuir. Dr. Carswell at a later meeting strongly urged that the question should be sent back to the Sewage Committee for further consideration, but in this he received scanty support. It was admitted that the bacterial method was suitable for small communities, but it was maintained that it was utterly inadequate for dealing with such a volume of sewage as that of Glasgow, amounting to sixty millions of gallons a day. We are at a loss to understand that argument when the sewage of a city like Manchester can be successfully dealt with on this system, and when there is good reason to believe that it will ultimately be applied to the stupendous problem of the sewage of London.

Public Works.

SEWERAGE.

The London County Council has agreed to lend the Battersea Borough Council £3395 for sewer and paving works.

The Heywood Town Council is about to spend £8600 in the drainage of the Heap Bridge District of the borough.

The Sherborne Urban District Council has under discussion proposals for the sewerage of the district, and for the disposal of the sewage on the septic system.

The Orsett Rural District Council has entered into a provisional agreement for the purchase of an acre of land for £300 for a pumping station for the draining of Stanford-le-Hope.

The plans prepared by Mr. T. B. Simmons, Sanitary Inspector to the Sherborne Urban District Council, for the reconstruction of the drainage system at the Sherborne Union Workhouse have been approved and sanctioned by the Local Government Board. The scheme includes, for the efficient flushing of the drains, the fixing of two automatic flushing tanks, one at the head of each of the main branch drains. The Sherborne Board of Guardians have further instructed him to prepare a specification of work required to be done in the construction of two inspection chambers, a ventilating shaft, and fixing an automatic flushing tank in connection with the drains from the isolation hospital at the workhouse.

The Rural District Council of Eastbourne has decided to undertake the sewering of Willingdon village.

At a recent meeting of the Devizes Urban District Council the chairman read Messrs. Dibdin and Thudichum's report upon the adaption of the sewage works to their system of sewage disposal. After some discussion it was resolved that as the estimate of cost included in one sum the addition to the cost of the filter beds, and the cost of a road all round the works, the necessity for which was not absolute, the Town Clerk be directed to write to Messrs. Dibdin and Thudichum, and inquire what sum they had allowed in their estimate for making the road, and that after their reply is received a meeting of the whole Council in Committee be called, which the County Medical Officer be invited to attend, when the merits and costs of the two schemes will be finally considered. It was also resolved to recommend the Council to sanction application being made to Messrs. Cameron and Co., to give an estimate for a second filter bed (an additional fee to be paid them if required), and that they be asked to state what amount was allowed in their estimate for the alternative gear provided for, which might possibly be dispensed with.

There has been presented to the Glasgow Corporation a memorandum by the City Engineer regarding the proposed sewage works at Dalmuir, setting forth the present position of the work, and embodying as far as possible the results of the bacteriological experiments at Dalmarnock, with the view of ascertaining to what extent bacterial methods are capable of application at Dalmuir, and, so far as possible, the relative costs of the system already adopted by the Corporation, and of the works necessary for bacterial treatment of sewage. The memorandum in its course states that the estimated cost of the various works required for the bacterial treatment of sewage at Dalmuir would stand:—Tanks, £220,000; bacteria beds, £1,330,000; pumps, £10,000. In addition, the extent of the lands belonging to the Corporation between the line of the Lanarkshire and Dumbartonshire Railway and the river, available for sewage works, is 100 acres, so that the capital sum of £1,560,000 would be increased by the cost of 30 acres of additional land required to provide room for the tanks and bacteria beds, railway sidings, roads, and other means of communication.

At the last meeting the Moffat Burgh Commissioners came to a final decision regarding a site for the proposed works in connection with the burgh sewage purification scheme—a question which, so far as the plans and site are concerned, has been a perennial topic of discussion for several years past. A letter was submitted from Messrs. Hope, Tod, and Kirk, W.S., Edinburgh, agents for Mr. J. J. Hope Johnstone of Annandale, in reply to an offer made by the Commissioners to purchase a portion of the meadow on the Ker lands lying between Old Carlisle-road and the river Annan, and extending to 1¼ acre, for a site for the proposed works. The communication stated that the proprietor was unwilling to sell the land outright, but was willing to feu the portion. The meeting unanimously agreed to feu the ground on the terms previously offered, viz., £8 per acre, with £5 per annum for way leave. The Clerk was instructed to publish the notices required by statute, and to ask the engineer (Mr. T. O. Niven, C.E., Glasgow) to prepare a plan for the inspection of the ratepayers, and to proceed with the works when the period of notice had elapsed. The scheme, which was adopted in May, 1898, and which has been delayed owing to the difficulty in securing suitable land, was one of three alternative systems reported upon by Mr. Niven, and is known as Mr. Dibdin's or the Sutton system for the biological treatment of sewage. The estimated cost of the scheme, exclusive of land and way leave, is £2200. There are no patent rights nor royalties connected with the system, and the cost of working and maintenance is reckoned at about £100 per annum.

An inquiry has been held at Portslade with reference to an application of the Portslade and Southwick Outfall Sewerage Board for powers to borrow £3700 for completing the joint sewerage scheme.

The Chipping Norton Town Council has received a letter from Exeter *re* the covering for the septic tank at the new sewerage works, and the company at that city strongly advised the Council for various reasons to adopt the closed or covered-in style of tank.

WATER.

The inhabitants of Birkdale have given their final adhesion to the Water Board Bill.

The Branston Rural District Council has resolved to take in hand the water supply of Potter, Hanworth.

We understand that Cheslyn Hay, in the Cannock Rural District, is to be provided with a public water supply at a cost of about £5000.

The Cockermouth Rural District Council has decided to spend £3200 in works of water supply for Gilcrux and Croscannonby, and £400 in drainage works for Dovenby parish.

The new Scone water supply was formally turned on in front of the Public Hall, Scone, last week. The opening ceremony was performed by the Hon. A. D. Murray, County Councillor for the village.

It is understood that the Rattray Police Commission has decided to ask Blairgowrie Water Commission whether it could supply the whole burgh (including Westfield) with water, and, if so, on what terms.

At a recent meeting of the Cheddar District Council, at Axbridge, a resolution instructing Mr. A. Powell, C.E., to prepare a scheme for supplying the parish of Cheddar with a pure and adequate supply of water was adopted.

Last week the South Darley Council held one of the most important meetings of its history, when it was decided to apply to the Local Government Board for power to furnish the whole of the extensive district with a good and wholesome supply of water.

The Corporation of Irvine seeks powers to introduce an additional water supply for the burgh, and to construct and maintain works, and to widen and improve a street. Powers are sought to use the water of the Caaf Water and Broadshaw Burn, and compensation water is allowed, amounting to 373 gallons per day for every acre of the surface area draining into the reservoir. The borrowing powers extend to £120,000 for the waterworks, and £5000 for the street improvement.

The Borough of Wolverhampton is about to considerably extend and improve its water supply, means of storage, and powers of distribution. The scheme has been prepared by Mr. Horatio Brevitt (Town Clerk). The Corporation will obtain its powers from a legal document which may be cited as the Wolverhampton Corporation Water Act, 1901, with which are incorporated certain other Acts affecting the question of water supply. This Bill it is proposed to promote during the course of the next Parliamentary session.

Promoters of the scheme for bringing down the Aldfield sulphur water to Ripon have not abandoned hope of carrying it into effect, a clause for that purpose having been inserted in the Corporation Bill, 1901, with a view to testing the feeling of the ratepayers. At a recent meeting the City Council discussed the advisability of issuing to the ratepayers the whole of the medical reports and details of the scheme prior to the meeting this month, at which a poll is sure to be demanded by one side or the other. It was agreed that this should be done, and a Committee, including those for and against the scheme, was appointed to draw up the report.

A Local Government Board inquiry has been held at Sevenoaks by Mr. H. H. North, with reference to the application of the Urban District Council for sanction to borrow £3000 for the purpose of dealing with the Bradbourne storm water, rendered necessary by the injunction granted by Mr. Justice Bruce in the case of Lambarde *v.* the Council.

Messrs. John Tubnbull, Jura, and Sons, consulting and hydraulic engineers, Glasgow and London, have signed a contract for the largest water power installation that has ever been established in Ireland. It is for a flax mill on the river Mourne, and includes the complete outfit for 1100 horse-power on a 16ft. fall. This power will be developed from five improved Hercules turbines placed vertically in steel cases, and transmitting their power to one line of horizontal shafting.

A public meeting was held at Rugby recently with reference to the Urban District Council's Bill for constructing additional waterworks for the supply of its district. In moving a resolution giving the necessary consent, Mr. Eden dealt with the history of the town's water supply, and said the demands of the mill owners and riparian proprietors rendered it necessary that further parliamentary powers should be obtained. At present the Council had power to take 400,000 gallons a day. The Council had purchased Brownsover Mill and land adjoining, and the suggested Bill would give power to spend £140,000 if necessary on the matter. The proposal met with strong opposition from four former members of the Council. Mr. Parnell thought a great deal of money was being spent unnecessarily. The town would get as much water as was needed for many years to come from the river Avon without going to Showell to construct a reservoir. Mr. Seabroke argued that the present population of the town should not be heavily taxed for the benefit of the future generations. The meeting was very protracted, and ultimately a proposal was made that it should be adjourned. This was put to the meeting, and negatived by 40 votes to 35, and the original motion was carried by 46 to 29. Mr. Parnell then demanded a poll of the town.

LIGHTING.

The new electric lighting scheme at Stockton, estimated to have cost £26,500, has been completed.

The London County Council has agreed to lend the Battersea Borough Council £20,000 for electric lighting purposes.

The London County Council has decided to lend the Woolwich Borough Council £20,000 for electric lighting and dust destructor works.

Messrs. Dick, Kerr, and Co., Limited, Kilmarnock, are to supply steel work and electric plant which the Portsmouth Corporation require. The contract price is £202,409 6s. 4d.

The Devonport Town Council have decided to authorise the promotion of a Bill in Parliament to acquire the gasworks undertaking. A meeting of owners and ratepayers will now have to be held and a second meeting of the Council before the final step is taken.

To meet the increasing demand for the supply of gas in Hull, the British Gas Light Company, Limited, have deposited a Bill for powers to enlarge their gasworks by the acquisition of over twenty acres of land adjoining their existing works at Sculcoates. For the purposes of exercising the powers sought under this Bill, and for the general purposes of their Hull Station undertaking, Parliament is asked to sanction the creation of £280,000 further capital, of which £210,000 is to be raised as 5 per cent. capital, and £70,000 by borrowing on mortgage at 4 per cent.

THE Edmonton District Council is meeting with some opposition to its proposal to join with surrounding districts in promoting a Bill to generate and supply electricity. A memorial, containing some 500 signatures, has been received against the scheme, and another is being extensively signed.

AT a recent meeting of the Long Eaton Urban District Council, the Council's Electrical Engineer submitted plans and specifications for an electric lighting scheme for the town, and it was decided to send the same to the Board of Trade for approval. It was also resolved to apply to the Local Government Board for sanction to borrow £15,000 for carrying out the scheme.

THE Finance Committee of the Bradford City Council has just drawn cheques to the value altogether of about £168,000 in connection with the purchase of the undertaking of the North Bierley Gas Company. The shareholders are being paid out individually, and between 400 and 500 cheques have been drawn. The largest holding amounted to about £4000 or £5000. The purchase cannot be completed until early in January.

NOTWITHSTANDING the strenuous opposition of two-thirds of the ratepayers of Sleaford to the electric lighting scheme, organised by a majority of the Urban District Council, the Local Government Board have followed the granting of a provisional order by sanctioning a loan of £7000 to carry out the project. The only restriction made is that the money shall be repaid in twenty-five years, instead of thirty. As only a two-wire system is to be used, it is urged by experts that should the town continue to increase as at present, larger works and the three-wire system will have to be substituted, thereby greatly adding to the outlay. The action of the Local Government Board in thus placing an unnecessary burden upon the ratepayers has given rise to great indignation on the part of the large ratepayers.

THE provost, magistrates, and councillors of the burgh of Ardrossan are seeking authority to erect, construct, and maintain new gasworks, and to construct and maintain additional waterworks, and for other purposes. The clauses dealing with the gasworks define the limits of the Provisional Order sought for to compromise and include the burgh of Ardrossan, the suburbs thereof, and places adjacent (excluding the burgh of Saltcoats) within the parish of Ardrossan. Clause 9 gives power for local authorities to purchase portions of the undertaking within their district. The illuminating power of the gas supplied by the Town Council shall not be less than sixteen candles. The powers for the erection of new waterworks are limited to a period of seven years. The borrowing powers for the gasworks do not exceed £40,000, and for the waterworks £60,000.

A BILL has been deposited in the Private Bill Office of the House of Commons to incorporate and confer powers on a company to be known as the Derbyshire and Nottinghamshire Electric Power Company. The company is to be established for the purpose of "producing and supplying electrical energy" within the whole of the county of Nottingham and the county of Derby, except that part of Derbyshire which lies to the south of the river Trent and to the north-west of the boundary between the unions of Bakewell and Chapel-en-le-Frith. The share and loan capital of the proposed company is fixed at £2,400,000, of which £600,000 may be raised by the issue of debenture stock, and £1,800,000 by the issue of £1 shares, but with the right to divide these shares into "preferred half-shares" and "deferred half-shares." The company ask for powers to proceed to acquire the lands authorised to be taken under this Bill as soon as £100,000 "of the capital of the company shall have been subscribed under contract binding the parties."

A BILL has been deposited for next session to incorporate a company under the name of "The Electric Power (Yorkshire) Company," for the purpose of supplying electricity "to authorised undertakers and to persons requiring a supply for power." The area of the proposed company's operations, as described in the Bill, is to comprise "that portion of the West Riding of the county of York which lies to the southward of a line drawn along the southern bank of the river Ouse from its mouth to the junction therewith of the river Wharfe, thence proceeding along the southern bank of the river Wharfe to the bridge over that river known as "Bolton Bridge," thence westwardly along the main road past Bolton Bridge Village, the "Devonshire Arms," Hambleton-cottages, Long Causeway and New Lathe to the bridge over the Skipton and Ilkley branch of the Midland Railway between New Lathe and Skibeden, thence along the Skipton and Ilkley Railway to its junction with the Shipley and Colne extension of the Midland Railway, and thence along the Shipley and Colne Extension Railway to the point at which that railway crosses the boundary between the counties of York and Lancaster. The share and loan capital proposed to be authorised by the Bill is £2,666,666, of which sum £666,666 may be raised by the issue of debentures, and £2,000,000 by the issue of £10 shares, with the right to divide the shares into "preferred half-shares" and "deferred half-shares." The company is not to put in force the powers contained in this Bill until £100,000 of the share capital shall have been subscribed.

GENERAL.

THE Bristol Corporation has resolved to construct an underground sanitary convenience in Old Market-street.

MR. W. F. H. CREBER has been appointed Engineering Assistant to the Derwent Valley Water Board, at a salary of £250 per annum.

THE Highways Committee of the London County Council has resolved to appoint an electrical engineer at a salary of £1000 a year, to deal with the reconstruction for electrical traction of the Council's tramways.

APPLICATION is to be made to the Local Government Board for a Provisional Order for the formation of the urban district of Grays and the rural district of Orsett into a united district, for the purpose of providing a joint hospital for infectious cases.

THE Edmonton District Council has passed a formal resolution to apply to the Local Government Board for sanction to a loan of £10,000 for the purchase of land at Hertford-road, for the erection of an infectious hospital, and also a small loan of £150 to cover the cost of conveyance, &c.

A LOCAL Government Board inquiry was held at the offices of the Bromley and Beckenham Joint Hospital Board recently, into an application by the Board for sanction to borrow the sum of £6500 for the erection of new diphtheria wards at the Infectious Diseases Hospital, Bromley Common.

THE Torquay Town Council has decided to offer to supply Teignmouth with a minimum of 15,000,000 gallons and a maximum of 25,000,000 gallons of water per annum, delivered by meter at the point of junction with the Corporation's main at or near Teignbridge, into a 7in. main to be laid by the District Council, thence to Teignmouth, for a period of fifteen years, at a charge of 1s. 1d. per 1000 gallons, meter rent £5 per annum, provided that the quantity supplied in any one day shall not exceed 200,000 gallons; and that this offer be open for acceptance within one month. In the event of the offer being accepted, the necessary steps will be taken to obtain power to raise the dam of the Kenwick reservoir at an estimated cost of £12,000.

A Local Government Board inquiry has been held at Queensbury with reference to the application of the District Council for sanction to borrow £2970 for main road and street improvements.

The Chesterfield Town Council has received sanction for promoting a street improvement Bill. The cost involved in the scheme amounts, it is estimated, to £177,000, and two new streets are contemplated, one being from Low Pavement to Holywell Cross, and the other from Gluman Gate to Sheffield-road.

A town's meeting at Portsmouth last week decided to celebrate the commencement of the new century by promoting a fund for the establishment of a sanatorium for consumptives on the southern slope of Portsdown-hill, overlooking Portsmouth. It is proposed to ask the Government, which owns the hill, for a site, and as the War-office contemplates building a large military hospital for the garrison in the vicinity, hopes are entertained that the answer will be favourable.

There was laid before a recent meeting of the East District Committee of the Berwickshire County Council at Ayton, a report by the County Sanitary Inspector on an outbreak of small-pox in the district. In October a woman, employed as a rag cutter in Chirnside-bridge Paper Mill, was certified to be suffering from small-pox, and was at once removed to the District Hospital for Infectious Diseases. A few days later the wife and child of a workman in the same department of the mill were also certified to be suffering from small-pox, and immediately after the husband himself became ill. The whole family was removed to the hospital. A young lad at Preston, about four miles distant from Chirnside, who had visited at the house of the latter family, was next laid down, and he too was speedily removed to the hospital. Here the nurse and caretaker were next seized, and in all there were nine small-pox patients under the care of the Medical Officer. The caretaker and one child died, while the other seven patients recovered. There has been no case since in the district. A question having arisen as to how the hospital is to be disinfected, the opinion of the Local Government Board is to be taken before the work is entered upon.

FORTHCOMING MEETINGS.

January.

Saturday, 5th.—Sanitary Inspectors' Association.—President's New Year's address.

Saturday, 12th.—Metropolitan Asylums Board resumes.

Monday, 14th.—Surveyors' Institution.—Ordinary general meeting. Adjourned discussion on "The Future of the London Water Supply," by Mr. R. E. Middleton. 8 p.m.

Tuesday, 15th.—Sanitary Inspectors' Examination Board.—Examination for Sanitary Inspectors, St. Stephen's House, Victoria Embankment.

Monday, 21st.—Surveyors' Institution.—Junior meeting. Mr. L. S. Wood on "Income Tax, Schedule A." 7 p.m.

Tuesday, 22nd.—London County Council resumes.

Thursday, 24th.—Society of Architects.—Sessional meeting. 8 p.m.

Dr. John Shepherd has been reappointed Medical Officer of Health for North Walsham, at a salary of £20 per annum.

Change of Address.—Mr. F. Redman, Civil Engineer, has removed from the Railway Offices, Newport-street, Swindon, Wilts, to more central premises at 34, Wood-street, Swindon.

Subject to the approval of the Local Government Board, Mr. J. H. Pearson, of Minster, near Ramsgate, has been appointed Inspector of Nuisances for the urban district of Broadstairs, at a salary of £100 per annum.

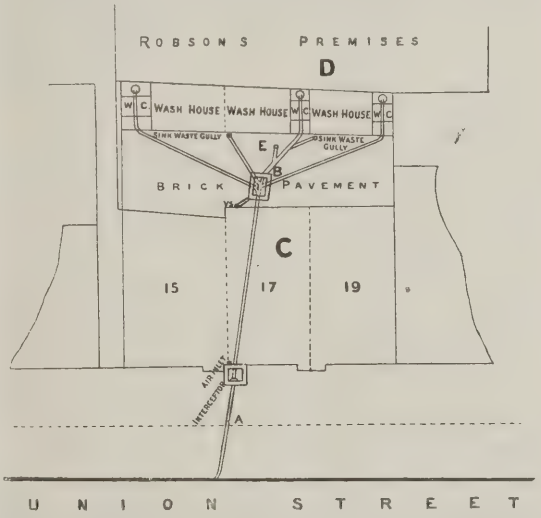
NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2055.—Hygiene: Teaching of, for Ladies.—"B. B." writes:—"I have obtained a first-class certificate from the Science and Art Department both in elementary physiology and in hygiene, and am now studying in the advanced stages for these two subjects. Will you please advise me (1) whether I ought to study any other subjects to qualify as a lecturer in hygiene? (2) If I obtained a pass in the honours stage, would that qualify me as a lecturer, or must I go through a course at the Ladies' Sanitary Association? If I qualify by examination as a lecturer, should I be able to obtain an appointment?"

Answer.—(1) If the candidate obtains a first-class certificate in the advanced stage in hygiene, she will be enabled to teach hygiene in classes in connection with the Science and Art Department. (2) If she obtains a certificate as a teacher under the National Health Society, she will be enabled to teach and lecture on the laws of health in classes, &c., in provincial towns and villages, and the Society will endeavour to secure engagements for her. For full information, however, she is advised to write to the Secretary, National Health Society, 53, Berners-street, Oxford-street, London, W.

2056.—Drain or Sewer: Premises within Same Curtilage.—"A. S. J." writes:—"My Council recently caused notices to be served on two separate owners to reconstruct defective drains on premises shown on plan, and marked C and D. At the time of service D.'s drainage was connected with C.'s system, and carried to the main sewer by the pipe A B. On receipt of his notice D. disconnected his drainage from C.'s system, and took his drain direct to the main sewer through his own property. My Council, therefore, served a new notice on C. to remove the defective drains and construct new ones as shown on plan. C. now declines to obey this notice, contending that the drain A B is a sewer, as since the disconnection of C.'s drainage it only



receives the drains of houses which are the property of one owner. You will notice that the premises of C. are enclosed by a high wall, the only entrance to the houses being by the front doors. Each house has a separate wash-house and w.c.; the yard at rear has no divisions. My Council carried out the work, and have demanded payment from C., who declines to pay. Will you kindly advise as follows:—(1) Whether under the circumstances you consider my Council can recover, and whether the drain A to B became a sewer immediately the drainage of D.'s property was disconnected? (2) Are the premises within the same curtilage?"

Answer.—(1 and 2) The Council should be able to recover the cost of executing the work in question, as the construction, in our opinion, is a drain and not a sewer, as the cottages are within the same curtilage—see Pilbrow *v.* St. Leonard's, Shoreditch (1895) 1 Q.B. 433; 59 J.P., 68; St. Martin's-in-the-Fields *v.* Bird (1895) 1 Q.B. 428. The duty to repair the drain is on the owners.

2057.—Inspectors of Weights and Measures: Books Required.—"J. J. G." writes:—"Would you be good enough

to inform me if there are any books published which will help me to qualify for an Inspector of Weights and Measures?"

Answer.—The following books will, we believe, be found useful: "Model Regulations with respect to Inspectors and the Inspection of Weights and Measures, and Weighing and Measuring Instruments," price 1s. 6d.; and "Examinations of Inspectors of Weights and Measures—Notice to Candidates and Heads of Examinations," price 2d.; Jamieson's "Elementary Manual of Applied Mechanics," price 3s. 6d.; and Balfour Stewart's "Lessons in Elementary Physics," price 4s. 6d. Any of the books may be obtained post free at the prices named from the office of this journal.

2058.—SANITARY INSPECTORS: QUALIFICATIONS. — "Old Reader" writes: "Please inform me what qualifications are necessary to become a Sanitary Inspector. Kindly also state whether a candidate has to pay any fees when sitting for an examination."

Answer.—We regret we are unable, for reasons of space, to describe what qualifications are essential in a person intending to become a Sanitary Inspector. The querist is, however, advised to procure Taylor's "Sanitary Inspector's Handbook," price 5s., wherein all the information sought by him will be found fully detailed. The book may be obtained post free from the office of this journal at the price named. The fees for candidates for the certificate of the Sanitary Institute are £4 4s., when the examination is held in a provincial town.

2059.—DELEGATION OF POWERS TO COMMITTEES OF DISTRICT COUNCILS.—"J. P. H." writes:—"Has an Urban District Council power under the Public Health Act to pass a resolution giving general powers to their Sanitary Committee to instruct their Inspectors to issue notices and take legal proceedings for the abatement of nuisances—in short, to delegate the whole of the nuisance clauses to the Sanitary Committee to deal with, without confirmation in each case by the whole Council?"

Answer.—This district is that of a Municipal Corporation, and Sec. 22 (2) of the Municipal Corporations' Act, 1882, applies. The section referred to empowers the Council to appoint out of their own number such and so many committees either of a general or special nature, and consisting of such number of persons as they think fit for any purposes which, in the opinion of the Council, would be regulated and managed by means of such Committees, but the acts of every such Committee shall be submitted to the Council for their approval. It is, however, apprehended that when the Council is acting under the Public Health Acts, and the Elementary Education Acts, such ratification is not necessary. (See Arnold's "Law relating to Municipal Corporations.") In the case of Parish, Urban, and Rural District Councils, similar powers of appointment of Committees are given under Sec. 56 of the Local Government Act, 1894, and this section enacts that "where a Committee is appointed by any District Council for any of the purposes of the Public Health Acts, or Highway Acts, the Council may authorise the Committee to institute any proceeding, or do any act which the Council might have instituted or done for that purpose other than the raising of any loan, or the making of any rate or contract." Under this section no subsequent confirmation by the District Council is required to the Acts of Committees except as specified. It therefore follows that if any one of the Councils named, *i.e.*, Borough, Urban, Rural, or Parish Councils, have delegated the full powers, as they are entitled by the Act, the Committee may institute legal proceedings in such cases as that named, and any minutes relating thereto do not require ratification.

2060.—SALE OF FOOD AND DRUGS ACTS: SANITARY INSPECTOR MAY TAKE SAMPLES.—"A. D. S." writes:—"I am an Inspector of Nuisances under an Urban District Council, and appointed with the approval of the Local Government Board. At the time of my appointment I was instructed to take samples of food, &c., under the Sale of Food and Drugs Acts, when and as I thought necessary. It is now considered by some persons that I have no power to act in that capacity. Samples of food, &c., are taken in this district for the County Council by the Inspector of Weights and Measures. Kindly let me have your opinion on the matter, having regard to Sec. 13 of the Sale of Food and Drugs Act, 1875, and Sec. 8 of the Local Government Board's Order of March, 1891. (2) Is any special procedure necessary for the appointment of an analyst? (3) Must the analyst for the district be the County Analyst; and (4) should the result of the analysis be set out in the form set forth in the schedule of the Sale of Food and Drugs Act, 1875? (5) Does any special power exist for any Inspector to take samples of milk, water, or other article of food for the purpose of ascertaining the source of infectious disease?"

Answer.—(1) An Inspector of Nuisances who is appointed subject to the approval of the Local Government Board, has his

65 and 67, Millbank Street, Westminster,

LONDON, S.W.

duties defined by the regulations contained in the Board's General Order of the 23rd March, 1891. Clause 8 of this Order prescribes that "the Inspector shall when and as directed by the Sanitary Authority, procure and submit samples of food, drink, or drugs suspected to be adulterated, to be analysed by the analyst appointed under 'The Sale of Food and Drugs Act, 1875,' and upon receiving a certificate stating that the articles of food, drink, or drugs are adulterated, cause a complaint to be made, and take the other proceedings prescribed by that Act." When, therefore, an Inspector has been generally or specially directed by a Sanitary Authority to take samples of food, &c., for analysis, no special resolution appointing him Food and Drugs Inspector is requisite, as he is already such by virtue of his appointment as Inspector of Nuisances. Sec. 13 of the Sale of Food and Drugs Act, 1875, also empowers an Inspector of Nuisances acting under the directions of the Local Authority, to procure samples of food. (2) No. Except in the case of boroughs having a population exceeding 10,000, and County Councils who have to appoint separate analysts. (3) Yes. Except in boroughs having a population exceeding 10,000. (4) Yes. (5) No. The provisions of Sec. 116 of the Public Health Act, 1875, and of Sec. 4 of the Infectious Disease (Prevention) Act, 1890, should not, however, be overlooked.

2061.—Medical Officer of Health: Residence in District.—"A Subscriber" writes:—"I shall be glad if you can point out any clause in a public Act or in a Local Government Order bearing upon the question of the residence within the district of the Medical Officer of Health or Sanitary Inspectors either as the same may refer to London or the provinces. I have been informed there is such a requirement in force, but have not yet been able to find the same."

Answer.—The only statutory provision is contained in the Public Health (London) Act, 1891, Sec. 106 of which provides that "every person appointed or reappointed after the commencement of this Act as Medical Officer of Health of a district shall (except during the two months next after the time of his appointment, or except in cases allowed by the Local Government Board) reside in such district or within one mile of the boundary thereof, and if, while not so residing as required by this enactment, he assumes to act, or receives any remuneration as such Medical Officer of Health, he shall cease to hold the office." There is no General Order of the Local Government Board, so far as we are aware, which prescribes that a Medical Officer of Health or Sanitary Inspector shall reside within his district.

2062.—Parish Constables: Appointment of: Parish Council may Obtain and Pay for Legal Advice.—"Subscriber" writes:—"An Inclosure Award of 1809 states that the Constable of the township annually is to sufficiently cleanse the public drains in the township, the charges and expenses whereof are to be borne by the several proprietors or occupiers upon the said inclosure by a rate to be laid by the Constable according to the Poor Rate of the said township. It seems the rate is to be on all the land in the parish. Please say (1) how should the Constable be appointed; (2) how the expenses of making and collecting the rate should be paid; and (3) if a Parish Council can obtain and pay for legal advice."

Answer.—(1) The Parish Council may appoint under the Parish Constables Act, 1872, one or more Parish Constables for their parish, and may in such resolution fix the amount of salary to be paid him or them. A copy of any such resolution is to be delivered to the Justices of the Petty Sessional Division comprising the parish, who may appoint a Parish Constable or Constables in accordance therewith—see Jenkins's "Law Relating to Parish Councils and the Local Government Act, 1894," price 10s. (2) See answer above. (3) Yes, but this cannot be done without a resolution being first passed by the Parish Council authorising the employment of a solicitor.

2063.—Flushing of Water-closets: Powers of Local Authority.—"C. M." writes:—"My Authority are considering the question of taking the necessary legal steps to compel the owner of a street of dwelling-houses to provide a supply of water in water-closets for flushing purposes, which are at present hand-flushed. I presume proceedings should be taken under Sec. 36 of the Act of 1875 for not providing a sufficient water-closet to each of the said houses. Could you give me any cases as a precedent where, in a similar action, proceedings have been successful?"

Answer.—If the Local Authority have adopted Part 3 of the Public Health Acts Amendment Act, 1890, they are empowered under Sec. 23 of the said Act to frame bye-laws as to the keeping water-closets supplied with sufficient water for flushing, so as to affect buildings already erected as well as to new buildings. Model bye-laws on the subject will be found in Mackenzie and Handford's "Model Bye-laws of the Local Government Board," two vols., price 25s., which should be perused. In the absence of such bye-laws, the Local Authority may proceed under Sec. 36 of the Act of 1875 if they determine, on the report of their Surveyor or Inspector of Nuisances, that the existing water-closets are insufficient. In Sherborne Local Board *v.* Bogle, Q.B.D., 18th March, 1880; 46 J.P., 675, the defendant was the owner of several houses, each of which had a water-closet attached to it. The water-closets had no flushing apparatus, and were flushed by pouring water from pails. The Surveyor of the Local Board having reported that the water-closets were insufficient, the Board gave notice to the defendant to provide sufficient water-closets, and on his failing to do so, executed the necessary works and proceeded to recover the expenses from the defendant. It was held that the Local Authority were entitled to recover the expenses incurred.

CHAPTER XV.—ELECTRO-MOTORS.

INDUCTION MOTORS.

If we take two semicircular pieces of iron, and by winding insulated copper wire round them in the manner shown in Fig. 25, and passing a current of

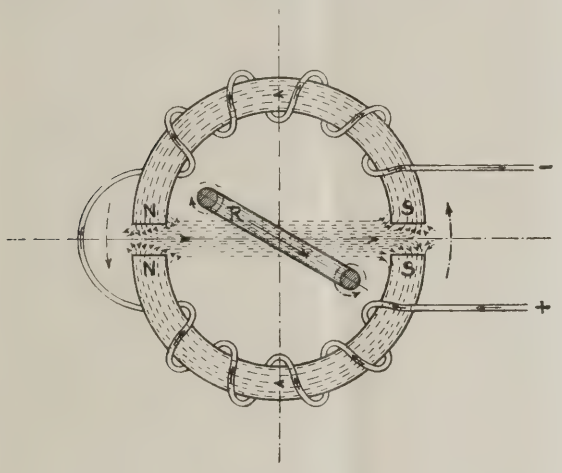

Fig. 25.

electricity through the wire, we produce two electro-magnets, having the two N poles opposite to each other, and likewise the two S poles opposite to each other; and the lines of force will have a tendency to traverse the air space intervening between the two poles, as shown by the dotted lines and arrow heads, thus producing a magnetic field between the two poles.

If we join these two semicircular magnets together the poles still remain the same, and the lines of force will take the same course from one to the other as before, so that the magnetic field remains unaltered.

If we now suspend a ring of copper or other conducting metal R, so that it is free to revolve inside the magnet ring and revolve the latter, so that the lines of force passing from the N to the S poles are cut through by the wire ring, magnetic lines of force will circle round the wire in such a direction that they resist the rotation of the magnet ring, and because the former is free to revolve, the latter drags it round with it and causes it to rotate, but at a slower speed, as otherwise no lines of force would be cut through, and magnetic lines of force would cease to circle round the wire.

This explains briefly the principle on which induction motors are worked, but although in these motors a rotating magnetic field is necessary, the magnets themselves do not rotate, for with two or more alternating currents of different phase a rotating magnetic field can be produced with stationary field magnets.

A three-phase induction motor has field magnets consisting of a laminated iron ring wound with three sets of coils, in the same manner as the armature of the generator shown in Figs. 16 and 18, each set of coils on the motor being connected directly with the corresponding ones on the generator. Fig. 26 shows the armature and field magnets of a motor in position, with the coils of both shown in section, the former, to avoid complicating the description, being shown as if each were wound only once round the core, instead of a great many number of times, as is the case in the actual machines; and the adjoining curves represent the character of the currents flowing through each coil at any moment during one revolution of the armature of the generator.

At a certain moment the current in coil 1, (1) is at its maximum pressure, while in coils (2), 2 and (3), 3 the currents are at half pressure; in coil (2), 2 growing and in coil (3), 3 diminishing. The currents flowing through the coils above the horizontal centre line are momentarily positive, while those flowing through the coils below are momentarily negative, and the lines of force travel through the iron core of the field magnets in the manner shown by the dotted lines and arrowheads, thereby producing a N pole on the left-hand side, and a S pole on the right-hand side.

As the armature of the generator continues to revolve, the currents flowing through the coils alter, so that a moment afterwards it has attained its maximum pressure in coil (2) 2, next moment in coil (3) 3, and after half a revolution in coil 1 (1) again, but reversed; so that those coils which are above the horizontal centre line have now a negative current flowing through them, and those below a positive current. Thus the current attains its maximum positive and negative pressure in each pair of coils, placed diametrically opposite to each other in succession, so that the N and S poles are constantly assuming a different position and travel right round the ring, whereby the magnetic field rotates just as if the magnetic ring itself were being revolved, and with the same speed as the armature of the generator which supplies the current.

The armature consists of a cylindrical laminated iron core, having a spindle on which it revolves, and a number of insulated copper wires or bars arranged on its outer surface, parallel with each other and with the spindle. These wires, or bars, are connected together at both ends on the face of the core by metal rings, or discs, one on

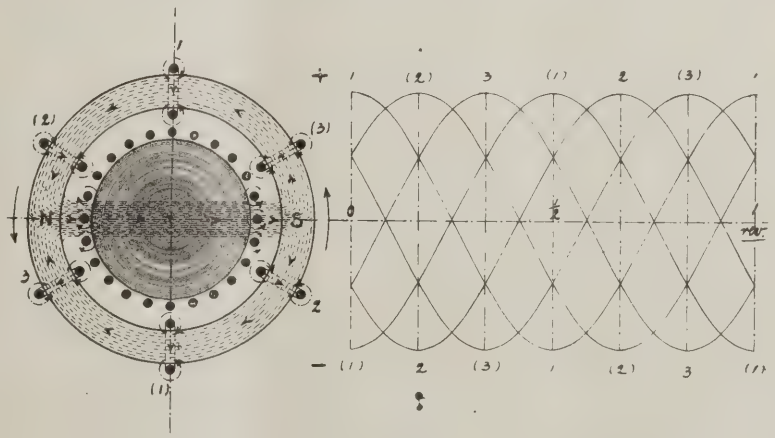

Fig. 26

each side, so that the induced current can flow freely from one wire to another; but they have no connection with the generator whatever, the current flowing through them being generated as the lines of force from the rotating magnetic field are cut through by the wires, thus causing opposing lines of force to circle round them.

Instead of connecting all the wires together so that the induced current can flow uninterruptedly from one to the other, they can be connected in groups to insu-

lated metal rings on the armature spindle, having brushes to collect the current connected with resistances through which the current is compelled to flow, whereby a portion of it is destroyed, and thus less current flows through the wires and fewer lines of force circle round them.

By means of a switch any number of resistances can be switched on, or all can be disconnected, allowing the full current to flow through the wires, whereby the speed of the armature can be regulated, this being especially necessary while starting and stopping with a heavy load, or, in fact, whenever starting and stopping gradually is desirable.

Two-phase induction motors are worked in exactly the same manner, only that two sets of coils are wound on the field magnets instead of three, the current being supplied by a two-phase generator.

Lately induction motors have been made to work with single-phase current, by splitting up the current into two portions, and retarding one portion so that it enters the motor a quarter of a period behind the other, thereby producing a second phase artificially while the motor is being started, and until it has attained its full speed, when it continues working with the single-phase current in its ordinary state, oscillating backwards and forwards between the two portions of the coils placed diametrically opposite to each other. These machines are not nearly so efficient as the two and three-phase, however, and they are liable to stop whenever a heavy load is suddenly put on.

(*To be continued.*)

SEWAGE DISPOSAL IN CALCUTTA.

By A. E. Silk,

Member of the Institute of Civil Engineers, Member of the Sanitary Institute, Sanitary Engineer, Bengal.

(*Continued from page* 4.)

CHAPTER III.—Method of Working.

The action which takes place in a septic tank is brought about by the anaërobic, and the facultative aërobic, microbes which break up the complex substances to be found in sewage into simple chemical compounds, liquid and gaseous. The sewage itself contains all the elements of its own destruction, and all the septic tank has to do is to afford a resting place where the microbes can carry on their work without interruption; this resting place is to be found in the thick mat or felt-like scum which forms on top of the liquid. The particles of organic matter when they first enter the tank sink to the bottom; then a minute bubble of gas forms on each small lump and lifts it up to the surface, where it discharges its bubble of gas and then falls to the bottom again, but probably not without first receiving a few thousand microbes, who will in their attack on the organic particles produce more gas and once more lift it up to the surface to procure more microbes. Owing to the slow current through the tank this up-and-down motion of particles does not take place in the same vertical plane each time, and there is thus a transference of particles in various stages of disruption and demolition from one end of the tank to the other, and it is more than probable that each time a particle of matter rises up to the surface to discharge its bubble of gas, not only does it receive an addition to the number of microbes, but even microbes of a different sort, and consequently the species of microbes that are to be found at one end of the tank are not to be found at the other. Bearing therefore these matters in mind, it leads to the conclusion that a septic tank must be brought into work slowly and by degrees.

A reference has been made to an unsuccessful experiment at Garden Reach; this crude experiment consisted in filling a barrel with night-soil from the mehters' buckets, and then leaving it to stand with the air excluded, as far as possible, for about a fortnight. That some change had taken place in the contents of the barrel was made perfectly evident by the absence of any smell and the change in their colour, but there was no liquefaction of the solids. The mistake that was made, of course, was not providing a collecting ground for the various kinds of microbes, and not providing means by which the particles of organic matter could be brought in contact with the microbes appropriate to the different stages of breaking up from solids into gases and liquids.

The septic tank was therefore first filled with plain water up to what had been fixed to be the normal level, namely, 4ft. 6in. above the floor at the outlet end of the tanks. Sewage was first discharged into the tank on the 22nd April, 1899, and it was kept at work continuously until the 1st May, 1900, or a period of over twelve months and through all seasons of the year. For the first nine months the sewage to be dealt with consisted of one stool mixed with three gallons of water, urine, and a small quantity of washing water, and the latrine was used on an average 220 times a day, so that about 750 gallons per day had to be dealt with. In the middle of January, 1900, the flushing apparatus was disconnected, and only sufficient water was used as would wash the stools out of the pans, and all the washing out was done by hand, so that the minimum quantity of water was used, and the sewage consisted of a mixture of one stool, half a gallon of water, urine, and washing water. Beyond being rather browner in colour, the effluent produced from this extremely strong sewage was to all intents and purposes the same in appearance as that produced from the weaker sewage. At all times there was a very strong evolution of sulphuretted hydrogen gas at the outlet valve, but it was quickly dispersed and was seldom if ever apparent within a distance of three or four yards; possibly, if arrangements were made for drawing off the gases and burning them, the smell at the outlet would be less. The outlet was so regulated that the discharge was continuous day and night, and this caused the minimum amount of disturbance to the contents of the tank: the velocity at the outlet end of the tank was practically constant. It is estimated that the solid fæces discharged into the tank during the year's trial would completely fill it up to the normal liquid level, but on opening up the manhole covers, after the contents had been run out very slowly indeed, only 12·5 cubic feet of sludge was taken out of the tank, equivalent to a depth of nearly 1in. over the whole floor. On testing the thickness of the scum in the grit chamber it was generally found to be about 6in. thick, but at the outlet end of the septic tank there was practically no scum at all. It is therefore, it is submitted, clearly proved that a septic tank has the power of liquefying night-soil in a perfectly satisfactory and inoffensive manner, for practically no sludge was found in the tank after a year's working, and the effluent as it issued from the tank seldom contained more than 13·3 parts per 100,000, or ·013 per cent., of solids in suspension. Samples of the effluent were taken from time to time for record, and although they smelt rather strongly of sulphuretted hydrogen for the first day, with the stoppers kept out of the bottles they quickly freed themselves of gas, and are now as clear, bright, and inoffensive as could be wished.

As this experiment was carried out within the precincts of the Presidency Gaol it was not permissible to introduce outside labour to control the working of the filters, and the *régime* had to be fixed by the hours

* *Vide* Report of the Sanitary Commissioner with the Government of India for 1898, page 277.

during which the prisoners were at work in the garden. It was not considered necessary to purchase automatic gear, for one of the objects of the experiment was to ascertain how far this system of disposal could be attended to by native labour without any special European supervision. From the commencement of the experiment at the end of April until the end of June the effluent was run on to the filters alternately for periods of twelve hours, and although the resulting filtrates appeared to be perfectly satisfactory, as far as appearance was concerned, the chemical analyses of them produced such astounding results* that it became necessary to alter the *régime*. From the end of June the tank effluent was allowed to pass straight through the filters without any period of rest in the filters; but the filters were changed four times a day. In July the effect of double filtration was tried by causing the tank effluent to pass first through two iron gutter pipes filled with furnace slag, and thence to drop down on to the filters; the effect of the double filtration will be shown in the next chapter, but as far as appearance was concerned no distinction could be made between a filtrate from a single cinder bed or that from two slag filters.

A Scott-Moncrieff filter, with its multiple filtration, was also tried; it was found to be a remarkably rapid deodorant, for the septic tank effluent entered it smelling strongly of sulphuretted hydrogen, but left it two minutes afterwards quite free of the gas and inoffensive.

The filtrates were all discharged into the low-level tank in the corner of the gaol garden. When operations were first commenced the tank was covered with a tangled mass of water-creepers, but these were all carefully cleared before the rains set in. During the rainy season the night-soil from the gaol is trenched on the eastern bank of this tank, and there is no doubt that a considerable quantity of polluted liquid from the trenching must have found its way into the tank, and consequently any nuisance that might arise from the tank could not be rightly attributed to the discharge into it of purified filtrates from the septic tank. As a matter of fact the tank has never given the slightest cause for complaint. During the rainy season the surface of the water always appeared clear and fresh, and during the cold and hot weather the surface has become covered with a healthy-looking aquatic plant. There are a large number of fish and water tortoises in the tank, and the favourite basking place of the former is at the foot of the small masonry ladder down which the filtrates are constantly passing.

As was done in the case of the effluent from the septic tank, whenever a sample was taken for chemical examination, a smaller sample was also taken for record; not a single one of these samples has given the slightest offence, and at the time of writing they are quite clear and bright, with a small deposit, probably of bacterial matter, at the bottom of each.

The filtering material that is in use at the present time is that which was originally placed in the filters, and it appears to be as good and as fresh now as ever it was. It was found that when the effluent from the septic tank had been allowed to run for any length of time on one spot, the filtering material got covered with a black sort of slime which looked rather offensive; it was found that all that had to be done was to turn the material over with a spade once or twice, or perhaps stop the filter for twenty-four hours, and the slime would quickly disappear. In the iron gutters fitted with slag, that have been already mentioned, this slime appeared to collect in larger quantities than elsewhere; on drying the contents of these gutters in the sun, this slime was found to consist mostly of fibrous matter, which, when dry, gradually disintegrated and got blown away as dust or washed into the filter, on the top of which the slimy slag had been spread, by the first downpour of rain.

No sewage fungus was ever found at the outlet from the filters. The cinder filters had occasionally to be run dry for a couple of days to kill off the "intestinal worms" which seemed to thrive luxuriantly in the recesses of the filtering material or anywhere else that was exposed to the light. If the filtrates were allowed to stagnate in the filtration wells, they became the breeding grounds of mosquitoes and dragon flies, for their larvæ was found in abundance. Except for these no other forms of life were observed during the experiment—no doubt many others might have been found by microscopical examinations, but it was not considered necessary to have these made.

(To be continued.)

* The analyses for albuminoid ammonia were eventually cancelled by the chemical examiner.

HOW TO CHECK DIPHTHERIA.

An outbreak of diphtheria at Summertown, in Oxfordshire, has recently been engaging the attention of the Local Authorities. As a consequence, a report on the outbreak was submitted to the Sanitary Committee by the Assistant Medical Officer of Health, Dr. Ormerod. The occasion was made the subject of an interesting statement, affecting not only the outbreak in question but such outbreaks in general, by Dr. Colbie, who said that in view of the widespread interest which was taken in this epidemic at Summertown, he should like to say a few words to show how satisfactory the report was, and to show how satisfactorily the Medical Officer of Health for the past few years had dealt with the question of diphtheria. In order to do this, he should like briefly to quote a few figures from the back numbers of their sanitary reports with regard to diphtheria, and to be absolutely fair he would put the bad with the good. During 1890 Mr. Winkfield reported for the first time for twenty years that there had been no death from diphtheria in Oxford. In 1891 the Notification Act came into use, and in that year nine cases of diphtheria in Oxford were reported, with three deaths. He wanted to call attention particularly to the

PERCENTAGE OF DEATHS.

In that year it was approximately 30 per cent. In 1892, instead of nine cases, they got 86, with 23 deaths, a percentage of 26; in 1893 there were 101 cases, with 32 deaths, being a percentage of 31; in 1894 66 cases were notified, resulting in 23 deaths—a percentage of 30; in 1895 there were 80 cases and 14 deaths, which was 18 per cent.; in 1896 46 cases of diphtheria were notified, and only five deaths occurred, which was a drop to 12 per cent.; in 1897 there were 19 cases and two deaths—10 per cent.; in 1898 30 cases were notified and five deaths resulted, which was 16 per cent.; in 1899 91 cases occurred and three deaths took place, which was 4 per cent.; whilst in 1900 131 cases were reported, and only two deaths occurred. This gave them a percentage for the year of only 1½ per cent. He thought it was quite worth while asking themselves for a few minutes how it was they had got this extraordinary lowering in the percentage of the death-rate of diphtheria. He would draw attention to one or two facts. When they had a heavy death-rate for diphtheria it meant that the cases had been severe, and in bad cases of diphtheria persons might be incapacitated for a great number of weeks and even months, and frequently

DIPHTHERIA LEFT BAD EFFECTS,

especially among young children, such as severe forms of paralysis. It was interesting to notice this extraordinary lowering of the percentage of the death-rate,

and how did they account for this? There were two factors, he thought, which were brought into play. He did not believe the notification from 1891 to 1895 at all represented the number of cases which actually existed, and for this reason. About that time medical men in Oxford used to come to their diagnosis of diphtheria by looking at the throat of the patient, and if they found a well-marked membrane they used to call it diphtheria. They knew now that that was by no means conclusive evidence, and that that only occurred in severe cases. They might get a simple form of sore throat, which in old days they would have passed over. They might examine bacteriologically and find the germ of diphtheria present, and he thought that was one reason why they had notified these mild cases, and by notifying them they had prevented epidemics. Another factor he should like to call attention to was that he did think they had been greatly helped by the

ANTITOXIN SERUM.

Cases had been taken early, and were searched more carefully than was the custom in former times, and when they got to the hospital they were taken and inoculated at once. He knew Mr. Winkfield, who had certainly the greatest experience of any man in diphtheria in Oxford, and who had assured him over and over again that since the introduction of the anti-toxin serum his anxiety had been immensely relieved, because he knew the cases would run a more favourable course. In connection with this he should like to say a word or two with regard to the sister University. Curiously enough, they had had a parallel epidemic at Cambridge, and he should like to show the difference in the quiet way in which they had been doing their work. He thought they had to thank Dr. Ormerod for the indefatigable manner in which he had acted in searching out these cases, and also the district nurses. When he noticed they had had an epidemic of diphtheria in Cambridge, he wrote to the Medical Officer of Health to know what they were doing. He told him that in the course of one month he had sent out seven circular letters to different districts, and had got the aid of a body of experts from the Pathological Laboratory of the University. He had received that morning a report from him, because at the

END OF A MONTH THEY KILLED THE EPIDEMIC.

He found in the report that they had sixty-two cases with five deaths, and a portion of it he should like to read to them. They went very thoroughly into the question as to how the epidemic arose, and they came to the same agreement as Dr. Ormerod. This was what they said: "That all other sources of infection may be dismissed from consideration, except that of social intercourse or elsewhere." They go on to say: "This successful check to a diphtheria invasion which might have attained overwhelming force at a season specially favourable to the disease, as shown by the many towns in England and Wales that have been assailed, has been due to the united efforts on the part of all persons concerned, viz., Prof. G. Sims Woodhead, the Professor of Pathology, by his sound and prompt advice; the assistance by his staff, especially Dr. Cobbett; and by the use of his material." He thought they might congratulate themselves just as much as the Cambridge people on having prevented a serious epidemic. There was one reason in this report which he thought Dr. Ormerod might have dwelt with a little greater force upon. He simply mentioned that

SCHOOLS WERE THE FOCUS

from which diphtheria spread. He thought it would have been wise if he had pointed out how this came about, and he proposed to say something on this point. They knew these children came to school at an age at which they were extremely liable to infection where infection was about. They knew also that diphtheria was spread generally from mouth to mouth, that was to say, the germ was in the saliva, that it is not spread through the air to the same extent as scarlet fever or measles. It was a sort of mouth-to-mouth trouble. In schools this was what happened. Among the girls they got a great deal of kissing, and if they watched a number of boys directly they began to play they commenced wrestling with each other, and got their mouths in close contact. Children of that age were great Socialists; they believed in the division of property. There were one of two ways in which teachers should be warned. For instance, there was a sweet called "a black drop," or something of that sort, made up of peppermint, and it had been noticed of children holding these Socialistic views that they passed the sweet round and each had a suck. They could imagine if A had first suck and had diphtheria germs in his mouth that it was quite easy to account for the others getting it. And in another respect

CHILDREN WERE SOCIALISTS.

They believed in the division of property. A child would sit down to do a sum; he would take his slate pencil, and in order to quicken his brain he put the pencil into his mouth, and afterwards put it back into his pocket. Another lad would borrow the pencil, and very often infection was carried in that way. And then there was the use among themselves of the same drinking cups. Now all this meant that what they could do was to get teachers to help, and that when they knew there were cases of slight sore throat in their schools they should be on the alert and inform the Medical Officer of Health. That had been exactly contrary to their custom up to the present. It had been pointed out in many formidable epidemics that school teachers, in order to show they had a good school average, had been in the habit of hunting up children, and where they had been away through illness, getting their mothers to send them back in order that the Inspector might find a high level of attendance. He felt sure if school teachers recognised the danger of young children with sore throats coming to school without being inspected by the Sanitary Authorities, they would do a great deal to check the spread of diphtheria.

A SPECIAL meeting of the Ilkley District Council summoned in accordance with a requisition of four of the members was held last week for the purpose of discussing the advisability of calling a public meeting to consider and vote upon several important projects at present before the Council. The first was the proposal now before the Council to purchase a site on the moors and to erect thereon a storage reservoir of a capacity of 8 million gallons. The objections to the scheme are that it is far in excess of the requirements of the township, and would involve an unwarranted expenditure. It was decided to call a public meeting.

THE Thorne (Doncaster) water supply question has now reached an acute stage. Over eight years ago Dr. Bruce Low (of the Local Government Board) reported that the water supply of Thorne and several adjoining villages was about as bad as it well could be, and recently the West Riding County Council have moved in the matter, insisting upon a better water supply being provided. At a recent meeting of the Thorne Rural District Council the whole question was discussed, and it was unanimously decided to ask Messrs. Fairbank and Son, C.E., of York and Westminster, to meet the Council on the 9th inst. and advise it as to the best means of providing a waterworks for the supply of Thorne, Hatfield, and Stainforth.

Coming Municipal Men.

XVIII.—MR. T. C. GOLDER, Borough Surveyor of Deal.

Mr. Thomas C. Golder is a native of Folkestone, and received both his education and early professional training in that well-known Kentish health resort. He was fortunate in being articled to Mr. A. W. Conquest, A.M.I.C.E., the Borough Engineer and Surveyor to the Folkestone Corporation, a gentleman whose abilities did much to raise the town to the high position it now occupies as a health resort, and whose death in his prime was greatly deplored. On the appointment of the late Mr. John White, A.M.I.C.E., to the vacancy, Mr. Golder became his assistant, being appointed on Mr. White's recommendation.

MR. T. C. GOLDER.

The works upon which Mr. Golder was engaged at Folkestone were of a varied and responsible character, and included large extensions of the sewerage system, embracing the construction of about two miles of large circular sewer to take the Cheriton drainage; long lengths of 6ft. × 4ft., and 4ft. 6in. × 3ft. 6in. brick culverts for the enlargement of the main sewers; also a high-level brick culvert, and the construction of a new 3ft. diameter outfall, carried out into the sea on iron piles. In laying out ornamental grounds and extensions to the Fever Hospital, Mr. Golder was also actively employed, and during his *régime* many of the main streets were paved with Jarrah wood blocks, and plans and estimates were prepared for the apportionment and making up of nearly twenty new private streets. The preparation of plans for, and the construction of, underground lavatories and other public buildings also occupied his attention.

Mr. Golder relinquished his appointment under the Folkestone Corporation to take up his present position as Borough Surveyor to the Corporation of Deal some six years ago, and in this capacity he has designed and carried out many works and improvements. One of the most important of these designs is the Central Deal Improvement, comprising a long length of sea wall, a promenade, and a new road, &c; a new ornamental bandstand, a shelter seat, large underground lavatories with baths, ornamental surface lavatory and baths for ladies.

In addition to these essentials of a growing health resort, extensions to various sewers, and the drainage of undrained roads, and widening and improvement of various public streets, necessarily provided Mr. Golder with congenial work. Nor has this been all, for new depôt buildings, including stables, large stores, stableman's house, cart sheds, and a mortuary have also occupied his time and attention. And last though not least, must be added his plans of an infectious diseases hospital, with the various essential blocks.

During Mr. Golder's time at Deal, the system of collection of house refuse has been entirely re-modelled to meet the requirements of a health resort, and he has also had under his supervision the sanitary inspection of the district, and the bringing of the house sanitation up to the requirements of the time. That the efforts have not been lost upon the Corporation of Deal is evident by the fact that they voluntarily increased Mr. Golder's salary about a year ago, and at the same time expressed their appreciation of his services.

Some idea of the progressive attitude of the Deal Corporation may be gathered from the fact that during the last four years the waterworks have been acquired compulsorily by the joint authorities of Deal and Walmer, the purchase price being about £63,000, and proof is not wanting to show that this has been a very successful undertaking; seeing that last year there was a profit of something like £500, which went towards the lessening of the rates at Deal, and this notwithstanding that considerable outlays were made in laying larger main supply pipes, and making extensions to the works.

After the acquisition of the water supply, the town then turned its attention to its drainage, and no less a sum than £40,000 has been expended on new drainage works including extensions to the sewers and the construction of a pumping station, a reservoir, and a new outfall, and these new works are now almost completed, so that the town of Deal in a few weeks will be second to none for the excellence of its water supply and its drainage.

During last summer Mr. Golder read a paper at the Town Hall, Deal, before the Association of Municipal and County Engineers, who visited the town, entitled, "Some of the Municipal Works at Deal," and after a discussion of the paper, which was well received, the members visited the various works, and were much interested in the same, especially the "Foreshore Protection Works," which comprised a number of groynes in front of the northern sea wall on the "case system."

With youth on his side, and an experience so varied, Mr. Golder may be said to possess unique chances of going forward in his profession, and in including him in this series we have every confidence that our anticipation in this direction will be fulfilled at no distant date.

THE HEALTH OF LONDON COUNTY.

In a brief note we last week referred to the issue of the annual report of the Medical Officer of Health for London (Dr. Shirley Murphy) in the year 1899. We also gave the summary of the births, marriages, and deaths, but we now propose dealing with these matters in greater detail. The greatest difficulty, however, which faces us in dealing with Dr. Murphy's report is the minuteness of the details set forth, and the seeming impossibility of condensing them without losing some facts of the greatest import to students of, and workers in, the domain of public health. It is only when there is placed before us such exhaustive and comparative tables as we here find, that we truly realise the greatness of the Metropolitan County.

Take, for instance, one of the first tables. In making a comparison of the death-rates, the eleven largest boroughs are given, but the population of all combined does not equal that of London. With a death-rate of 19·6 London takes the fifth place in this list, the first being held by West Ham with 17·2 and the last by Liverpool with 25·6. In the diagram showing the deaths from all causes, we see the remarkable improvement which has been maintained in the health of London for the past thirty years. Taking the period from 1841 to 1899 inclusive, we have a mean death-rate of 22·6 per 1000. From 1841 to 1871 only in five years did the annual rate fall below the mean, but from the latter year to 1899, it has only exceeded it twice, viz., in 1875 and 1878. Thus in the last decade alone thousands of lives have been saved, as seen by the following table:—

Period.	Mean lives gained.	Life capital gained.
1891-4	1042	79,606
1891-5	1304	85,519
1891-6	2461	104,742
1891-7	3587	142,460
1891-8	4161	161,331
1891-9	4095	172,763

Many other tables are given, in which the returns are thoroughly analysed, and several interesting facts brought out. From the general Dr. Murphy goes on to the particular, and there follows an exhaustive inquiry into the deaths arising from the principal zymotic diseases. The rates from these for the past ten years are:—

1891	2·27 per 1000.
1892	2·80 ,,
1893	3·04 ,,
1894	2·65 ,,
1895	2·62 ,,
1896	3·11 ,,
1897	2·56 ,,
1898	2·77 ,,
1899	2·46 ,,

The number of deaths from the principal zymotic diseases, viz., small-pox, measles, scarlet-fever, diphtheria, typhus, enteric, ill-defined fevers, and diarrhœa, was 11,174, giving an annual rate of 2·46 per 1000. The eastern group of districts had the highest mortality from the principal zymotic diseases in 1899, viz., 3·17 per 1000 living, and the western the lowest (1·91). Among the sanitary districts, St. George, Southwark, had the highest death-rate (4·53), and St. Martin-in-the-Fields the lowest (1·07). The deaths from small-pox numbered 3 in 1899, and 7 deaths were attributed to "cow-pox and effects of vaccination." The number of deaths from measles was 2141, as compared with 3077 in 1898. The vaccination returns show that the number of children "unaccounted for" continues to increase. In 1875, the percentage of such cases on the total number of births was 8·8; in 1880, and in 1885, 7·0; in 1890 it had risen to 13·9; in 1895 to 24·9; and in 1897, the latest available returns, 29·1. It will be some time yet before we shall be able to rightly judge the effect of the new Vaccination Act in this direction.

In the distribution of measles mortality in London throughout the year 1899 the eastern group of districts had the highest death-rate, and the western the lowest. Among the sanitary districts St. George-in-the-East had the highest death-rate (1·20), and Plumstead and Paddington the lowest (0·05). During the first quarter of the year the measles mortality in London was 0·34 per 1000 living; the death-rates in the northern, central, and eastern groups of districts exceeding this average. During the second quarter of the year the measles death-rate in London rose to 0·61 per 1000 living; the death-rates in the northern and eastern groups of districts being above the London average. In the third and fourth quarters of the year the London death-rate declined to 0·47 per 1000 living; and the eastern and southern groups of districts were above the London average in each of these quarters. In each quarter of the year the eastern group of districts had a measles death-rate considerably in excess of the London average.

The cases of scarlet fever notified during 1899 numbered 18,224, compared with 16,920 in 1898. The number of deaths registered from this cause in 1899 was 398, compared with 581 in 1898. In the distribution of scarlet fever mortality in London throughout the year 1899 the central group of districts had the highest death-rate (0·11), and the eastern group of districts the lowest (0·06). Of the districts, the mortality was highest in Rotherhithe (0·27), and lowest in St. Giles and St. Martin-in-the-Fields. During the first quarter of the year the southern group of districts had the highest death-rate (0·11), and the central group the lowest (0·03); during the second quarter the western group of districts had the highest death-rate (0·11), and the eastern the lowest (0·04); during the third quarter of the year the central group of districts had the highest death-rate (0·12), the death-rates of the northern, eastern, and southern groups being equal, viz., 0·07 per 1000 living; during the fourth quarter of the year the central group of districts again had the highest death-rate (0·20), and the eastern group the lowest (0·07).

In Plumstead early in the year there was a small epidemic of scarlet fever, and Dr. Davies, the Medical Officer of Health, could not exclude the milk supply as a possible source of the disease; one firm of wholesale vendors practically refusing to tell him the source of their supplies. Through his recommendation the attention of the Local Government Board and the London County Council was called to this fact, the latter body endorsing the view that all vendors, wholesale or retail, should be compelled to declare the sources from which they receive their milk. Without this power it is very difficult to trace possible means of contagion. An inquiry was also made into the prevalence of scarlet fever at various periods of school attendance. From the 28th to the 31st week of the year, 1472 cases among children were reported; in the 32nd to 35th (the holiday period) 1172; and the first four weeks of return to school (36th to 39th) 1688. After this it will be difficult for anyone to deny the absolute necessity for the exercise of greater care in sending children to school from infected homes. September and October are the black months of the year for scarlet fever, the number of cases, at all ages, being considerably above the mean during these two months. With but few exceptions, the notifications received during the first five months were below the average.

The cases of diphtheria notified in 1899 numbered 13,711, compared with 11,883 in 1898. The number of deaths registered from this cause in 1899 was 1946, compared with 1760 in 1898. In the distribution of diphtheria mortality throughout the year 1899, the

southern group of districts had the highest death-rate (0·55), and the western group the lowest (0·26); of the several districts St. George, Southwark, had the highest death-rate (1·04), and St. Martin-in-the-Fields the lowest (0·08). How persistently infectious is diphtheria is shown by a case quoted. A child who had suffered from diphtheria in the Fountain Fever Hospital was discharged in the middle of August. She went to Leytonstone for a month, returning to Fulham in the middle of September. Her mother contracted diphtheria, and was removed to the hospital on October 2nd. The girl returned home and slept with the father, who suffered from diphtheria, on October 23rd. On October 21st the child went to stay with some relatives in another street in Fulham, and on November 6th her cousin developed diphtheria. Shortly after this she went to visit an uncle and aunt at Kingston-on-Thames both of whom were attacked with diphtheria. Reporting on this extraordinary case, the local Medical Officer says that "Several bacteriological examinations were made, and the bacillus of diphtheria was found on every occasion in the nasal secretion until the end of January, though both the throat and nose appeared perfectly healthy."

There were 1728 fatal cases of whooping-cough in 1899 against 2160 in 1878.

A considerable space is devoted to enteric fever. During the year the number of cases notified was 4467, an increase of 1436 on the previous year. The deaths were 759 against 554. The highest death-rate was 0·43 in the City, and the lowest (0·04) in St. Saviour. A review is given of the remarks made by the various Medical Officers on the circumstances surrounding the outbreaks in their respective districts. Several point out possible causes, but others have failed in their attempts to discover any reason for the advent of enteric into their divisions. In several reports, moreover, illustrations of the communication of this disease from one person to another are given. The experiences of enteric fever in 1899, as, indeed, that of previous years, points to the spread of enteric fever from cases of this disease, the nature of the illness of the first case not being recognised. It further shows the risk of the retention of cases of enteric fever in the houses of poor persons when the conditions of life are such as to give opportunity for extension of the disease. The only recognition of enteric fever, the use of the Widal test in all doubtful cases, the isolation of the sufferer, and the employment of persons beyond middle life to attend upon the sick, all are needed to limit such spread of the disease. The year 1899 was characterised by excessive prevalence of enteric fever in the latter part of the year. There was marked increase above the average in the 40th-46th weeks, the increase being most manifested in the 43rd, 44th, and 45th weeks. Thus there was a marked increase in the number of cases notified in the 40th week (week ending October 7th), a fall in the 41st week, and from that time a rapid rise in each successive week—42nd, 43rd, and 44th. The prevalence showed a trifling decline in the 45th week and a rapid decline in the 46th week, after which the fall in each successive week (with one exception) was continuous and rapid. This excess of prevalence was manifested over wide areas of London, both on the north and south of the Thames, the districts on the north of the river which were most affected being those in the east of London. It is interesting to observe that some difference in the relative proportion of males and females attacked is observable in the year 1899 when compared with the two preceding years. Thus in 1899, in the four weeks 42-45 the proportion of females attacked was greater than in the rest of the year, in 1897 and 1898 it was less in these four weeks than in the rest of the year. It will be seen, therefore, that in 1897 and 1898 the proportion of females was less in the weeks in question than in the remaining portion of the year, and that in 1899 the position was reversed. When the proportion of females over 15 years of age in the four weeks in question in 1899 is compared with the proportion in the corresponding period of the two preceding years, it is found to be somewhat smaller. Thus the number of females over 15 years of age per cent. of total females attacked was in 1897 69·3 per cent., in 1898 67·1 per cent., and in 1899 65·1 per cent. Again, when the lists of notified cases of infectious diseases are examined, it is found that secondary cases in invaded houses were greater in 1899 than in the preceding two years. Thus the proportion of secondary to total cases in the latter six months of each of these years was—1897 8·7 per cent., 1898 8·9 per cent., 1899 10·9 per cent.

Summing up the matter, Dr. Murphy says that in connection with possible causes of the behaviour of enteric fever in 1899 it is deserving of notice that floods in the rivers did not precede the increase under consideration as in 1894, when they preceded an increase which I believe was due to pollution of water supply. There was, however, in the large excess of cases in the 43rd, 44th, and 45th weeks, suggestion that some undiscovered infected food supply was contributing to the total prevalence which occurred during these weeks. As the result of considerable inquiry in those districts in which the prevalence of the disease was most marked, I have been unable to obtain any evidence indicative of a particular common cause of enteric fever in the weeks mentioned. Apart from the increase in these weeks, there was larger autumnal prevalence of this disease than in any recent year, and it may be stated that during the last few years there has been increasing autumnal prevalence, probably due to natural causes.

The deaths attributed to influenza, which in 1898 numbered 1283, rose to 1817 in 1899, the corrected annual average for the preceding ten years being 1272. The deaths attributed to bronchitis numbered 9195, being 1008 below the corrected annual average for the preceding ten years; the deaths from pneumonia, however, were 597 in excess of this average, and numbered 6666. The deaths from phthisis were 8291, giving an annual rate of 1·88 per 1000. Mortality from all causes, from phthisis, and from all causes other than phthisis, increases with overcrowding, and that the maximum increase from diseases other than phthisis occurs somewhat earlier in life than the maximum increase from phthisis, while in this diagram the conditions under which the inhabitants are housed as far as can be considered, it must be recollected that the population which is badly housed suffers from other consequences of poverty than insufficiency of dwelling accommodation. But however much these other conditions may contribute to the production of phthisis, there is ample reason for thinking that the dwelling itself and the manner in which it is occupied are important factors in determining the prevalence of this disease. It is interesting to consider in this connection the measures which are now in the main relied upon for the cure of phthisis. They consist in the placing of the patient by night and by day under conditions which are mostly widely different from, and, indeed, are directly opposed to, those which obtain in the overcrowded tenement. In so far as these measures are successful in effecting the cure of phthisis the overcrowded dwelling must be deemed to promote the disease, and hence the effects of overcrowding upon phthisis mortality may be understood.

Three cases of bubonic plague were reported, but happily they were successfully dealt with, and at no time was there any possibility of the disease being spread in the port of London.

The West Bridgford Urban District Council has resolved to establish a refuse-destructor, to erect some cottages and stables, and to enlarge its sewage farm.

THE COLLECTION OF HOUSE REFUSE.

By A. Taylor Allen, Mem. Soc. Engineers,
Portslade-by-Sea.

The law relating to the collection of house refuse and the consideration of a system of collection, whether by contract or direct, affects every Municipal Authority. Under Sec. 42 Public Health Act, 1875, every Local Authority may undertake or contract for the removal of house refuse, either for the whole or part of their district, and under Sec. 44 of the same Act, they may make bye-laws imposing the duty of carrying out such work on the occupier of any such premises, but under Sec. 26 Public Health Amendment Act, 1890, this power is more favourably extended, as under that section they may impose such duties on occupiers as will *facilitate* the work of collection.

Consideration should first be given to the question whether the Authority should make bye-laws under Sec. 44. It is a matter of considerable importance that all refuse and excremental matter should be removed from houses as often as practicable; it must be borne in mind that in districts where very few of the houses have sufficient garden ground for the proper disposal of such refuse, considerable difficulty will be experienced when the duty is imposed upon the occupiers.

In urban and populous rural districts it is very essential that the Local Authority themselves should remove all house refuse to ensure its frequent and regular removal, and prevent both nuisance and constant risk of injury to health, and when this is the case it is well that the Authority and their officers should be acquainted with Sec. 43 Public Health Act, 1875. "If the Local Authority themselves undertake or contract for the removal of house refuse from premises, and fail without reasonable excuse after notice in writing from the occupier of any house within their district requiring them to remove house refuse within seven days, the Authority are liable to a penalty not exceeding 5s. per day."

The writer is strongly in favour of the direct system, that is, the Authority doing the work themselves with their own horses and staff, and the use of properly constructed covered carts or vans.

The disadvantages of the contract system, that is, the Authority letting the contract to a local contractor, is that often the horses employed are anything but a credit to the town, and the men uncivil, the latter being accounted for by the reason that such contracts are generally made for one year only, and the men disliking the work have no reputation to sustain and do not stay long enough to become acquainted with the work. (Here the writer may remark that he cannot see why "dustmen" should not be provided with a suitable uniform for their work as are Inspectors, firemen, and other officers of the Council.) With the contract system there is always experienced a difficulty in getting the work done expeditiously and as regularly as it should be, and the men are not so directly under the control of the Surveyor or Inspector as they would be if done by their own staff.

The system adopted in some towns of placing the refuse in tubs or iron receptacles for collection in the early morning is faulty in case of a wind blowing the lighter refuse away, and the contents of the receptacles being overhauled and overturned by people who are in the habit of picking out materials for selling as a mode of livelihood.

Where the Local Authority undertake the work on the contract system, it is very important that a definite specification and form of tender should be drawn up, and the writer submits an abridged specimen.

Specification.

Generally.—The person whose tender shall be accepted, hereinafter called the contractor, is to covenant for himself, his executors, and administrators for a period of . . . years from the date of the signing of the contract, to effectually collect, remove, and take away in suitable carts, all dust, including dirt, ashes, clinkers, cinders, shells, vegetable matter, and rubbish of every description that may be found deposited in any ashpit, dustbin, or like receptacle belonging to any dwelling-house in the urban district of . . . . on such days as the Council or their authorised officer shall from time to time direct, and shall execute all such directions, and abide by any regulations that may be necessary for the execution of the work.

Horses, carts, and implements.—The contractor to provide, at his own expense, all horses, carts, labour, brooms, baskets, shovels, ladders, implements, and utensils of whatsoever kind may be necessary for the proper execution of the work and the prevention of any nuisance arising therefrom.

The contractor shall employ only such men as are honest, steady, and civil, and able-bodied.

The contractor shall employ good, well-bred, strong cart-horses, with proper and suitable harness, and shall provide all food, water, forage, shoeing, and every requisite necessary for keeping the horses and tackle in satisfactory condition.

All horses, carts, and men shall be subject to the approval of the Council, and the Council or their officer may from time to time summarily dismiss any horse or cart which in their judgment is unsuited or unfitted for the work, or men who shall act in an improper, uncivil, or offensive manner to any officer of the Council or any inhabitant of the district.

Solicitation of money prohibited.—Neither the contractor or any of his men shall be entitled or permitted to solicit from any of the inhabitants of the district or their servants any money, reward, beer, or other drink, for any duties performed under this contract.

Negligence of contractor.—In case of any failure or omission of the contractor to fulfil his contract, the Council shall have power, after giving twenty-four hours notice to the contractor, to collect, remove, and cart away any dust or refuse, to employ some other person or persons to execute the said work, and the contractor shall, on demand, pay to the Council all costs and expenses incurred in doing the work so neglected or omitted to be done by him.

All notices to the contractor shall be duly served upon him if given to, or left for him at his residence, and may be signed by either the Surveyor, Inspector of Nuisances, or Clerk for the time being of the Council.

Contract not to be sublet.—The contractor shall not assign or dispose of the contract, or any part thereof, or sublet to any person or persons whomsoever.

Contractor's responsibility.—The contractor shall take the risk of all accidents of any kind whatsoever happening to any horses, carts, or men employed under the contract, and shall be chargeable for any contract done by them, and shall, at his own expense, reinstate and make good all or any injury or damage which may happen by reason of the execution of the work, whether such injury or damage may occur to any house or building, or any matter or thing therein, or to any highway or footpath in the said district, and he shall indemnify the Council from all actions, lawsuits, damages, and expenses which the Council may be subjected to.

Payments.—Payments to be made to the contractor by quarterly instalments, subject to deductions as aforesaid (if any).

Disputes.—Any question arising as to any matter or thing arising out of or incident to the contract shall be left to the Surveyor, whose decision shall be final and binding on all parties.

Form of Tender.

..... the undersigned hereby tender to supply horses, carts, and men, and collect, remove, and carry

away all dust and refuse of every description in and from the several houses, buildings, and premises within the district of the ..... Urban District Council, according to the specification, schedule, terms, and conditions of contract, for, and in consideration of the sum of ..... pounds ..... shillings. And..... hereby undertake to execute a contract for the due and proper performance thereof, and ..... prepared to find sureties to your satisfaction.

Dated this ..... day of 190

Profession or calling.....

The above might require a little modification in certain districts as regards tips and disposal of refuse. The author wishes to point out that there is no statutory definition of "house refuse," and the Local Government Board are not prepared to advise as to what may or may not be included in the expression in the varying circumstances of particular cases. Whether shop refuse should be included with house refuse has caused much agitation in some districts, and for the benefit of readers, the writer gives a summary of information received from thirty-eight cities and towns :—

27 collect shop refuse generally.
2 collect it in small quantities.
9 do not collect it.

Therefore, about 75 per cent. collect shop refuse out of the 38 cited above.

23 make no charge.
3 charge for large quantities.
2 charge on an average of 2s. per load.
1 charges 10s. per quarter.

It may also be noted that 8 out of the 38 are in possession of refuse destructors, 3 use it to raise low-lying ground, while the remainder tip and burn it.

The writer is of an opinion that much delay and inconvenience would be saved if Local Authorities could adopt a card system with "D" or "Call" printed on, and the date and day the dustman should be expected in this particular street, so that any occupier having dust could place their card in the window.

THE FIRST MUNICIPAL CREMATORIUM.

The first crematorium erected by any municipality in England was opened at Hull last week by the Mayor (Alderman Gelder) in the presence of an assembly representative of the public life of the city, including clergymen and ministers of all denominations, medical men, and members of public bodies. The Mayoress, Sir James Reckitt, Sir Robert Craven, Councillor S. Cohen (chairman of the Corporation Burial and Parks Committee), and a number of ladies, were amongst those present.

Occupying a site adjoining the Hedon-road Cemetery, through which entrance is gained to it, the crematorium is a red brick building in the early perpendicular style, freely treated. It comprises a hall, or chapel, 24ft. square, a second room containing the incinerating chamber, and a tower 70ft. high.

The cremating apparatus is a furnace of the regenerative type, designed by the late Mr. Henry Simon, president of the Manchester Crematorium Society. The degree of heat can be regulated in the most exact manner. There is no smoke and little visible flame before the body is introduced, and if the coffin is made in accordance with the regulations there is no smoke and no noise during cremation. The process occupies about an hour, at the end of which there only remain the inorganic bases of the bones, in the form of silvery-grey pumice-like fragments. These are removed by passing an asbestos brush through the chamber, which causes the remains to fall through an opening into the urn which is to receive them. The interior of the cremating chamber is, of course, at no time visible to mourners. The charge for cremating residents within the city is £1 1s., for other persons, £3 3s. These charges include storage of cremated remains for a period of twelve months. The cost of the crematorium has been about £2500.

Councillor Cohen, after some introductory remarks, presented a gold key to the Mayor, who opened the door, and the company were admitted into the chapel. Here, at the request of the Mayor, the Rev. Dr. James (St. Thomas's, Hull) read a portion of Scripture, and the Rev. Joseph Robinson (Wesleyan) offered a short prayer.

The Mayor, in declaring the crematorium open, said this was quite a new departure in municipal undertakings. It was only within a recent period that powers were given to municipalities to establish crematoria, and it was gratifying to know that in this respect Hull had led the way. The example was being followed by other municipalities. Last year several obtained powers, and this year many more were approaching Parliament in the same direction. People who had not studied the question might not realise how necessary an undertaking like that was in a large city. When they came to realise that at least half-a-million people died in one year in the United Kingdom, they would at once see how that might be a serious menace to the health of those who lived in the large cities and towns. Especially was it so in Hull. He knew of no other place where steps should be sooner taken to restrict as far as possible the burial of the dead in the cemeteries—for this reason, the subsoil was of clay, which was wet in winter and depressing to all to bring their dead to; and in summer the heat caused the ground to crack and emit gases which were a distinct danger to the public health. Therefore if they could take any steps to restrict interments they would be doing a great public service. There were, of course, prejudices against cremation, and possibly the greatest at the present time was the religious one. People would not be educated readily, but he could quite realise that after a certain period of education it would become quite a common occurrence for people to be cremated rather than buried. The Authorites in Hull had no desire to force the pace. They did not want the citizens to imagine that cremation was compulsory; but they did want to provide a place for those who, in the interests of sanitation, desired cremation rather than burial. It might be years before it would become a popular form of disposing of the dead. They were just at the dawn of a new century, and if he might venture to prophesy, he should say that before its close it would become the only form of disposing of the dead in this country.

The company were then shown the procedure for the admission of a body into the incinerating chamber, and urns were also exhibited. The crematorium was tested on Saturday, the carcase of a sheep being incinerated. All that remained were a few bones, which were placed in one of the urns for inspection.

At the close of the ceremony the company adjourned to the Town Hall, where tea was served.

The Municipal Council of Hay (Australia) has decided to improve the water supply by adopting the recommendation of the Government engineer to erect two new duplex pumps to lift 40,000 gallons per hour, a new boiler, and an additional storage tank of 100,000 gallons capacity. The plant will be placed near the irrigation pumping station, and water will be pumped direct from the river. The estimated cost is £6800.

THE BACTERIAL TREATMENT OF CRUDE SEWAGE.

The third report of Drs. Clowes and Houston on the experimental intermittent treatment of London crude sewage at the coke beds at Barking and Crossness has reached us. The first report was issued early in 1898, and dealt with the sewage as it arrived at the outfalls at Barking and Crossness. This was followed by a second report, giving the results obtained by the chemical and bacteriological examination of the crude sewage and of the effluent from the coke beds at Crossness. A supplementary report on the deposit found upon the coke of the coke beds was issued in October, 1899.

The present report gives a similar statement of the results obtained in the experimental bacterial treatment which has been carried out at the northern outfall (Barking) and of the experimental treatment carried out at the southern outfall (Crossness) since the issue of the last report. The superintendence of the chemical work has rested in the hands of Mr. E. Brooke Pike, the chemist at the northern outfall, and of Mr. J. W. H. Biggs, the chemist at the southern outfall, and the successful carrying out of the processes has been due to the careful work of these gentlemen and to the co-operation of Messrs. H. Stokoe and E. J. Beal, superintendents at the outfalls. The bacteriological work has been in the hands of Dr. Houston, who makes a separate statement of his results.

The process employed at both outfalls has been that of "intermittent contact" with frequent aëration of the coke surfaces. The acre coke bed at the northern outfall has received an effluent resulting from sewage which has been mixed with solutions of lime and iron sulphate, and has then been subjected to sedimentation. The smaller coke beds have received sewage which has not been mixed with chemicals, and which has, as a rule, not been freed from its suspended solid matter by sedimentation. Since the cellulose substances in the suspended solid matter of the sewage are only dealt with slowly by the bacteria in the coke bed, they tend to accumulate on the coke and to diminish the sewage capacity of the bed; they also tend to diminish the extent of purification from the dissolved organic matters of the sewage. Hence the acre bed, which receives the effluent from chemically-treated and sedimented sewage, has yielded better results than the smaller experimental beds. A very rough process of sedimentation of the sewage, without the use of chemicals, was effected at the southern outfall by allowing the crude sewage to flow through a large tank on its way to the coke bed. This sedimentation considerably retarded the choking of the coke beds.

Last Christmas an experiment was made on the whole of the South London sewage by allowing it to flow at a comparatively rapid pace through one of the large settling channels at the outfall works. In this way the larger portion of the solid suspended matter of the sewage was deposited; a portion of the effluent from this sedimentation process was treated in a small bacterial coke tank and was found to undergo the usual amount of purification, and to furnish an almost clear and entirely inoffensive and non-putrescible effluent. No reduction in the capacity of the coke bed occurred during the period of experiment. From this experiment it may be inferred that simple rapid sedimentation of the crude sewage on the large scale, followed by intermittent bacterial coke treatment will furnish an effluent suitable for the lower river, together with a sludge deposit which could be dealt with in the usual way. It seems reasonable that the experimental treatment of the sewage by rough screening, followed by rapid sedimentation without the previous introduction of chemicals, might now be attempted on a larger scale, and that by this means an effluent of much greater purity than that at present discharged might be sent into the river.

The general result of experience with the various coke beds has been that they increase in efficiency as the duration of their service increases, and that some considerable period of service is necessary before they exert their maximum amount of purification of the sewage. Dr. Houston summarises the previous reports issued by the Council, and gives details of the bacteriological work which he has carried out since the issue of those reports. As regards the general bacteriological aspect of the treatment of London sewage, Dr. Houston gives a statement of the conclusions at which he has arrived after two years' study of the problem on behalf of the Council. From this it is made evident that Dr. Houston concurs in the advisability of adopting the bacterial method of treatment of London sewage in place of the chemical treatment, and maintains that under the conditions existing in the lower river and at the outfalls, this system of treatment would furnish a more satisfactory result. But he states that although the effluent from the bacterial beds would not lead to nuisance in the river, it would be by no means a satisfactory liquid to introduce into a part of the river which was used for drinking purposes.

A PIONEER IN SANITARY SCIENCE.

Sir William MacCormac called attention, in a letter to the *Times* last week, to the services rendered to sanitary science by the venerable Sir John Simon. He said:—"In 'The *Times* History of the Century,' and for the year 1849, some allusion might well have been made to the all-important and epoch-making work of Mr. (now Sir John) Simon, in the development of sanitary science. In the first leading article of the *Times* of November 8th, 1849, you say:—'If any number of this journal ever deserved to be rescued from the usual fate of ephemeral publications, and regarded as a "possession for all time," it is that of yesterday. Contrary as it is to our practice to devote so many columns to one subject, unless it be a parliamentary debate, the extreme gravity of the topic in this instance, and the extraordinary interest of the documents by which it was illustrated, decided us to publish them simultaneously and entire. Mr. Simon's annual report to the City Commissioners of Sewers is unquestionably the ablest most lucid, and most temperate statement of our sanitary condition and wants that it has been our fortune to peruse, and we are greatly mistaken if it is not the programme of an earnest movement and the foundation of a substantial reform.' Your prevision has been realised, and the expectations of the writer of the article have been more than fulfilled. Sir John Simon may be truly said to be the creator of sanitary science in all its modern aspects, and his work has stimulated and guided the civilised world. Sir John Simon was a great surgeon, and preceded me in the office I now hold of President of the College of Surgeons, and to him it has been given to exercise an untold influence in the furtherance of the public health and the prevention of diseases. It is not possible to over-estimate the value of his labours. To give one example only, it is sufficient to look around and to note that London has become the healthiest great city in the world."

The Leeds City Council has unanimously resolved to promote a Parliamentary Bill empowering it to make additional waterworks and for other purposes, including the making of a crematorium, the consolidation of the city securities, and the adoption of the mansion on the Harehills Estate as judges' lodgings.

Sanitary Inspectors' Associations.

LONDON.

The usual monthly meeting of the Sanitary Inspectors' Association was held on Saturday last, at the Carpenters' Hall, London Wall. Mr. W. H. Grigg, the chairman of the Council, presided, and those present included Messrs. Warwick, Jordan, H. Alexander, T. G. Dee, Legg, Wallis, Baxter, I. Young, Ashdown, W. W. West, Langster, E. Tidman (hon. sec.), &c.

THE PRESIDENTSHIP.

After routine business and the election of a number of members,

The Chairman explained that the usual New Year's address would be delivered by Mr. W. W. West, of Walthamstow, an old and highly-respected member of the Association. This was a departure from the custom of many years' standing, that the president of the Association should deliver that address, but he regretted to inform the members that it was impossible for their president, Sir Hugh Gilzean Reid, to discharge this annual duty. Sir Hugh had quite broken down in health, and had gone abroad, and he doubted if they would see him again for a long time to come. Under the circumstances Mr. West had kindly stepped into the breach, and would give them an address which was in every way up to the standard. It was a curious thing that of the four presidents the Association had had, two should have been lost to them by death, namely, Sir Edwin Chadwick and Sir B. W. Richardson, and two by a complete breakdown of health, viz., Sir John Hutton and Sir Hugh Gilzean Reid.

SANITARY IDEALS FOR THE CENTURY.

Mr. W. West, who was well received, in addressing the members, said that he had no startling or brilliant suggestions to put forward, but he desired to ask their attention to a few thoughts on "Sanitary Politics." During the latter half of the century that had just closed, sanitation had taken giant strides, and the work of remedying the bulk of the bad conditions which prevailed had been put well on the way. Half a century was not a great period in the history of a nation, and the difference between the conditions prevailing fifty years ago and the conditions prevailing to-day were a subject for intense gratification. Food, drainage, the construction of dwellings, water supply, infectious diseases, had all been taken in hand, and the grosser evils at any rate removed. A good deal of the present work of sanitary inspectors was due to the greater refinement of opinion and sentiment, delightful to the thoughtful citizen, and worlds above the every-day notions of fifty years ago. Granted that a vast improvement had been effected—an improvement indicated by the reduction of the death-rate in London to about 18 per thousand—what is the question which most presses for settlement to-day? As the dying German philosopher is said to have cried for "Light, more light," so the anæmic, enervated dwellers in our cities to-day cry for "Air, more air." Overcrowding in cities is our trouble. There had been an enormous reversal of our mode of life from the open air of the countryside to the close confinement of towns. This was the subject which most agitates the minds of sanitarians as requiring their best efforts for a solution. The suggestions for modifying the evil could be divided into two categories—those which aimed at palliating the unwholesome conditions, and those which dealt with the evil radically by abolition. In default of removal all would assist in ameliorating, but amelioration had been tried to a greater or less extent with varying, but on the whole small success. For instance, the minimum air space allowed for rooms is necessarily fixed so low as to leave the great bulk of the trouble untouched, and even a determined enforcement of the law did not materially lessen overcrowding. Model or artisan dwellings did not much assist, for the designers of schemes prided themselves on the fact that they made provision for as many or more inhabitants on the cleared space by lifting them nearer the clouds. The fundamental principle of modern sanitation was prevention, and therefore they had to consider what should be done towards that end. He thought they must conclude in favour of those principles which spread out the populations, such as the erection of model villages in the suburbs, with the provision of rapid and cheap transit, and the removal of many manufactories to rural districts. Politics being taken to be the methods by which a policy is effected, sanitary politics like others must have a policy, which in order to succeed should have definite recognised principles. In the endeavour to secure the adoption of the preventive measures he had suggested, objections and difficulties would be met with at every step; but with definite principles to guide them, considerations of the problems would be assisted to a sound judgment. Now the foundation of all solutions of these great sanitary problems would be found in the Latin phrase "*Salus populi, suprema lex.*" If they insisted strenuously, in season and out of season, that the welfare of the people is the highest of all laws, and to assist the work couple with it the maxim suggested 2000 years ago by the teacher of Nazareth. "Whatsoever things ye would that men should do to you, do ye even so to them," there need be no doubt in their hope that the century now commencing would be as full of advantages or more so than the century which had just ended. Well might the Prince of Wales, at a gathering of sanitarians, ask, "If preventible, why not prevented?" The answer was that the principles he had suggested were not acted upon. There was no other law for sanitarians than that of the welfare of the people. It was said the prevailing bad conditions were brought about as the result of the working of economic law; then the economy must be a false one, and a new one should be put in its place. Men of all shades of politics had said that the working of the land laws was responsible largely for the evils with which sanitarians had to deal. If so, then amend the land laws. In advocating reforms of the character he had described they would be told that they were advocating rank socialism. But they must not be afraid of mere words and idle phrases, for they were but endeavouring to put into practice the principles which underlie all sanitary measures. (Loud applause.)

A spirited discussion ensued, and on the motion of the Chairman, seconded by Mr. I. Young, a hearty vote of thanks was accorded to Mr. West for his address, and the usual private conference of members followed.

For some years the Corporation of Eccles has had before it a scheme for the improvement of Timothy-street and the courts and alleys adjoining. A scheme to demolish all the property and rebuild having been rejected, the Committee appointed to deal with the matter have now submitted a further report. The area contains 141 houses, chiefly occupied by the working class. Since the first scheme was rejected forty of the houses have been condemned as insanitary, and compulsory closing orders issued. The Committee report that the owners do not now intend to stand in the way of the Corporation dealing with the property, and in most cases are prepared to accept a sum which would yield them an income equal to that at present obtained from the property. The Committee has had an interview with an assistant secretary to the Local Government Board, and now recommends the Council to adopt a scheme with this object.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

JANUARY 10, 1901.

HYGIENIC LOCOMOTION.

IT is significant that the first few days of the New Century should have been signalised by another triumph for electricity. The Metropolitan District Railway has long borne an unenviable reputation for discomfort, and its badly-ventilated tunnels have for years been patiently endured by the long-suffering public, who have been compelled, against their will, to make use of this medium of transit. The announcement that the company has resolved to supplant the present method of steam traction, with its sulphurous and noisome fumes, by electrical motive power, will consequently be hailed with undiluted satisfaction by every Londoner. The reason of this important step, which is to be proceeded with at once, was not so much the question of giving the people a healthier mode of travel for health's sake, as affright at the success of the Tube system, which it was feared would enter into competition with and seriously affect the profits of the shareholders. Nor, perhaps, is it reasonable to suppose that when a company is concerned influences other than those of £ s. d. would be likely to carry weight. But luckily for the health of the people, compulsion often comes to the rescue when indifference retards progress, and the promoters of the Tube deserve our best thanks for having rendered the indirect service to the public of making the present position of the District Railway untenable.

Some premonition of what was likely to come was furnished by a successful preliminary experiment between Earl's Court and Kensington High-street, and when we find experts such as Sir J. Wolfe Barry and Sir William Preece sanguine in the matter of its success, we may safely leave the mechanical work of conversion to the ability and skill of the engineer. But the practicability of the scheme we have never for a moment doubted, while its superiority over the existing arrangements from a health point of view have all along appealed to us as being both desirable and imperative. On one occasion it was stated in all seriousness—no doubt by a shareholder—that the atmosphere of the Underground, so far from being innocuous, was positively health-giving; but such a premise was opposed to all the laws of hygiene, let alone of common sense. How many victims these subterranean vaults have claimed will never be known, but we dare aver that indirectly they are numbered by thousands. Such a menace to health should have long ago been consigned to the limbo of things impossible; and it speaks ill for public enterprise in England that its toleration should have been endured till now. In view, however, of what is about to happen we may perchance let "the past dead bury its dead," cheered by the contemplation of a new era wherein health will no longer suffer, and comfort and convenience hold sway. And it is equally consoling to think that this movement in favour of electric traction will not stop short at the transformation of the Underground Railway, but that wherever similar undertakings exist a "rattling of the dry bones" will be heard.

No matter what the sceptics may aver or the ignorant contend, electrical traction is the traction of the future. On every hand the same trend is evident. Trams, 'buses, and every other species of conveyance are gradually but surely coming under its influence. And we hail its latest victory with all the more satisfaction because we see in it the precursor of a universal adoption of electricity, which is undoubtedly one of the most potent agents in the preservation of health which the past century has given to posterity.

A XIXth Century Product.

In concluding its annual review of the progress made in sanitary engineering, the *Engineer* makes some pertinent remarks on the development of the sewage problem. We are justly reminded that when considering the whole question of sewage disposal it is borne in upon us more and more that Nature never intended man to live together in large numbers or to stop continually in one place. As long as he is nomadic there is no sewage to worry about. Congregation in towns makes primitive methods of disposal on the site where produced out of the question. An abundant water supply does not add to the ease with which the problem may be solved. The employment of cesspits in towns—though their action in the country may be eminently efficient—is impossible with safety unless they are frequently cleansed. This process even is attended with disagreeable concomitants. At the beginning of the nineteenth century there was no proper method of sewage disposal. "In London," says the writer, "the cesspit was in extensive use, and the overflow went into stinking ditches, where the fluid remained stagnant and spread disease. It was illegal at the beginning of the century to turn sewage into the various streams flowing into the Thames in London, or into the river itself. Indeed, water for drinking purposes was taken from the river both at Charing Cross and London Bridge. The permission to use these streams for sewage rendered matters better for the time, but the river gradually got into such a foul condition that in spite of the rigorous measures since taken both above, in, and below the City, the river has by no means recovered its ancient purity. London is, however, wonderfully healthy and well drained, and in a much better condition than Paris, in spite of its larger population. Other cities have the same troubles, and they are meeting them in their own way. Sewage disposal as we now know it is, without question, wholly the growth of the nineteenth century; and far advanced as is the science of to-day as compared with what it was one hundred years ago, the matter is still only just in its infancy." All, we think, will agree with this conclusion. Much as we do think of the bacterial treatment, which has received such prominence in the closing decade of the century, we are not sure that it provides the final settlement to the problem. It is more economical in its use of land, but it still requires too much. A possible solution may come in the development of mechanical means of filtration and treatment. The engineer has overcome greater difficulties, and it may be that it is to him that we must look for the next great move in this all-important matter.

What will the London Boroughs do?

There are many public matters to which our contemporary the *Lancet* has rendered excellent service by the appointment of special commissions, conducted as they are by experts. Many phases are inquired into which are passed over by the superficial observer, and the result is that an unbiassed and judicial report is obtained which is of far greater value than the *ex parte* statements of the ordinary newspaper man. Its latest effort has been directed to the housing question in London, and the conclusions arrived at fully confirm what we have often stated, viz., that the crux of the question is largely one of rent; and that even when this is overcome, there is a certain class who will decline to avail itself of better conditions, because of its innate dislike of the restraint necessary to secure healthy houses. In concluding his report the special commissioner points out that of late years the whole problem has presented itself in a comparatively speaking novel aspect. It was supposed that the lowest class lived in low-class dwellings that were so insanitary and dilapidated that the first thing to be done was to pull the houses down. In many instances this is no longer the case. They, on the contrary, live in modern houses of the middle-class type that possess no structural defects and are well drained. But the tenants overcrowd these houses, and such is their poverty, and their dissolute, drunken, dirty habits, that in spite of good drainage and good houses the death-rates in certain areas of this description are generally above 40 per 1000 per annum, and have sometimes exceeded 50 per 1000. It is proposed to make this high death-rate the pretext for municipalising such property; but if the compensation given to the owners of such property is sufficiently high, will not this constitute a premium to those who allow their property to be degraded by the advent of tenants of this class? "Are Borough Councils competent," it is asked, "to become the landlords of the most dissolute and unmanageable section of the community? It is a heavy responsibility, though it is difficult to see by whom else the work can be undertaken. The London County Council shrank from the hazards of such an undertaking: will the Borough Councils display greater courage and enterprise? If the rents are to be reduced — and surely they must be reduced — the profits will be too small to tempt private enterprise. At first the strict regulations and the constant inspection that will be necessary to keep such property in order will have a tendency to drive away the more dissolute among the tenants. They will prefer to pay higher rents to the private speculator who will allow them to overcrowd and to wallow in the dirt which they often much prefer to cleanliness. But when the Local Authorities are able to provide, at low rents, proper accommodation they will then be justified in prosecuting those who prefer to live in insanitary conditions."

Private v. Public Ownership.

The last paragraph of the report discusses the *pros* and *cons* of municipal as opposed to private ownership. And here it is that the great reform is needed. At present a premium has to be paid upon the inflated value given to overcrowded dwellings by the exorbitant rents obtained by private landlords. When this is made impossible, Local Authorities will be able to attack the housing problem with some hope of

success. Social reformers must never forget that high rents are as effective cause of high death-rates as defective drainage, since the high mortality occurs where the drainage and structure of the houses are not at fault, where the streets are broad and the open spaces behind the houses are ample. Of the submerged, those who have sunk deepest in the mire stand first in need of municipal intervention on their behalf. It is in catering for them that private enterprise has most conspicuously failed, and therefore municipal enterprise would be most justifiable. Private enterprise only succeeds because it tolerates overcrowding. Private enterprise which only prospers by breaking the law may well be suppressed. If it can compete with municipal enterprise that observes the law, well and good, if not, it does not deserve to exist. Private enterprise subdivides into tenements a house worth £40 a year and charges £90 a year to the sub-tenants. Municipal enterprise need not charge more than £40 or £45 a year for the same tenements, and it can do this without increasing the rates. "Why, then," asks our contemporary, "should London wait? All that is necessary is to so arrange matters as to prevent the payment of such exaggerated compensation or purchase money as would handicap municipal enterprise by entailing too large an expenditure of capital. For instance, if a house worth £40 a year brings in £90 a year because it is subdivided into small tenements and overcrowded by the lowest class of tenants, the compensation for expropriation should be estimated on the £40 annual valuation and not on the £90. On this basis the re-housing even of the poorest and the most dissolute class could be made to pay, and from the sanitary point of view it is for this class that action is most urgently needed. From the moral point of view, though some of these people dearly love the dirt and disorder in which they live, others, on the contrary, would eagerly profit by any opportunity of raising themselves. In this cause, therefore, the social reformer and the sanitary reformer can press forward hand in hand."

Sanitary Condition of Sydney, N.S.W.

THE latest report to hand by the Australian mail does not indicate a satisfactory state of affairs in Sydney. Notwithstanding the plague visitation the Authorities do not appear to have fully realised their responsibilities. One of the advantages held out to emigrants is that on going to the Southern Cross they go to an almost perfect climate, but what is the use of this if filth and garbage are permitted to rot in the thoroughfares of the cities and round the houses of the people? In reporting on the health of Sydney for the quarter ending September 30th, 1900, Dr. T. Mailler Kendall, stated that the number of deaths from diphtheria, phthisis, diarrhœa, and typhoid fever showed a marked increase, being 166 in advance of the corresponding period in 1899. And he asserted that this high rate would continue so long "as the present system of scavenging and the removal of house garbage existed. The rubbish receptacles required re-modelling in order that the emanations from decomposing matter might not pollute the city." Later on he said that "the barbarous municipal muck-heaps were merely the perpetuation of ancient and bad sanitation, and could possibly be held responsible for the diphtheria mortality." There is nothing in this to attract recruits to the city where the celebration of New Commonwealth have just been held; the worst part is that all these dangers might have been removed long since. There is wealth in abundance, but this is of little value if the people are denied the privilege of living under healthy conditions.

Reorganisation of the Army Medical Service.

THE report of the Special Commission on the treatment of the sick and wounded in South Africa is expected to be issued very shortly, and speculation is already rife as to its probable character. Nothing has been allowed to transpire, so that most speculations may be regarded as pure guesswork, but we hear it stated, on what appear to be fairly reliable sources of information, that the report will be found completely to dispose of the sensational fabric of charges built up by Mr. Burdett-Coutts and his backers. If so, the nation will only be too glad. At the same time there can be no question that any complete scheme of army reform must include a reorganisation of the Army Medical Service. The strain on the resources of the country during the present war has, of course, been altogether exceptional, when the services of civil surgeons and medical men were requisitioned to a large extent. But as it is possible that such an emergency may recur at some future date, it behoves us to see that the organisation of the Medical Service is put on a thoroughly satisfactory basis, so as to be capable of meeting any demands that may be made upon it. The whole subject was exhaustively discussed at a recent meeting of the East of Scotland Tactical Society in Edinburgh. Setting aside the reserve which was natural in view of the pending report of the Royal Commission, many important suggestions were made. Professor Annandale, who presided, said that there should be a reserve of qualified medical officers to supplement the Royal Army Medical Corps. Such a reserve would naturally be associated with the reserve force—the Militia, Yeomanry, and Volunteers—and that could be supplemented by a certain number of specialists retained by the Government for the purpose of being called on if required, or of giving advice in special circumstances. Professor Chiene also threw out a suggestion that there should be an Imperial force or department, and that both in the old country and in the Colonies there should be a body of men and women chosen for their special knowledge in the treatment of disease and injury, the prevention of disease and the nursing of the sick. Every hospital in the country should, he thought, be asked to supply physicians, and surgeons, and the same would hold good with regard to ambulance associations for the supply of orderlies,

and nursing institutions for the supply of nurses and sanitary bodies for the supply of Sanitary Inspectors. For all of these would be required in a properly equipped and efficient medical department. The problem will be so to link such a force — chiefly drawn from the ranks of the civil population—with the army, as to make it readily available in times of crisis for service in the field abroad.

Private Bill Procedure in Scotland.

THE new Act regulating the procedure for Scottish Private Bill Legislation is now in full operation. There has been a rush of Provisional Orders lodged under the new procedure, which appears to be much appreciated and is likely to be taken advantage of. Several of the Orders contain no specific money provisions, but those in which authority is asked to raise capital or to obtain borrowing powers involve a total of £6,090,120, which is a considerable increase over last year. Of this amount it is to be noted that railway undertakings only account for £1,487,120—no doubt owing to the high price of coal and labour, necessitating a halt in railway enterprise. But electric lighting, water gas, and improvement schemes are responsible for the large total of £2,753,000. The new procedure will be peculiarly appropriate for the smaller towns, the Authorities of which will be encouraged to develop many much-needed schemes of public improvement. The statute empowers the Chairman of Committees in the House of Lords or the Chairman of Ways and Means in the House of Commons to exclude from its operation any provisions of a Provisional Order which are deemed to be of such a character or magnitude, or raise any such questions of policy or principle, that they ought to be dealt with by Private Bill, instead of under the new procedure. Under this power many of the larger undertakings will no doubt be reserved for the consideration of Parliament. But it may happen that what is called an "omnibus" application by a Corporation, containing miscellaneous provisions of a minor character may also have tacked on to it provisions involving important questions of policy or principle, and in that case there is some uncertainty as to how they will be dealt with. It will probably be found possible in such a case to split the less important from the more important provisions, reserving for the former at least the full benefits of the new procedure by local inquiry.

A Japanese University for Women.

THE *British Medical Journal* informs us that steps are being taken for the erection of a University for women in Tokio, which, it is hoped, will be opened in the spring of this year. The fact speaks volumes for the enterprise and progressiveness of the Japanese. There seems to be considerable demand among Japanese young ladies for university instruction, not only in the faculty of medicine—which is hardly surprising—but also in the Polytechnic School, an institution for the training of civil engineers! If Japanese women are about to embark on the latter profession they will set an example to their sisters in the West, and open up a new sphere of activity; but whether the sphere will be thought one suitable for women, or whether the example will be likely to be followed, are questions about which many will have their doubts.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

I THINK it is only right to admit considerable improvement has been effected in the matter of erecting guide posts and direction posts in country roads since the establishment of County Councils. There is, however, still room for very radical reform. Why is it that one finds, so commonly, guide posts—which should be painted in a conspicuous colour, and discernible and legible on a dark night — with posts, arms, and letters in dark colours, which neither can be deciphered nor seen immediately after sun-down? Is it not possible for surveyors to exercise a little more intelligent discrimination in regard to the matter, and erect guide posts to serve the purpose for which they are intended? One might assume that they never experienced the annoyance of finding themselves on an unfrequented road in a strange district on a dark night, and groping for a guide post at the junction of two roads. A few experiences of this kind would assuredly inculcate wisdom.

GUIDE posts and arms should always be painted in white or light stone colour, and the letters should be black—if raised letters so much the better—and the painting should be renewed every two years. Cast iron arms, unless screwed on to a backing of wood tenoned into the post, should not be used, as they are always liable to be broken by mischievous youths. The design of the posts and arms in numberless cases is execrable, and the designs, too, of manufacturers of such posts are generally lamentably bad, and consist of hideous arms fixed to ugly cast iron columns, terminating in a stumpy manner a few inches above the arms.

WHAT is really required is a simple uniform system for the position of guide posts with letters of a uniform size and posts of one pattern, and painted, as I have said, in a light colour, which should be prescribed either by County Councils or by statute. Every road junction should have a guide post, on which should be lettered the name of the parish in which it is erected, and the arms should not only indicate the direction of the village to which they refer, but also the nearest important towns and the distances thereto.

THERE are few municipalities, in my opinion, which enter into the spirit of their work *con amore* so much as that of Glasgow. The originality of the Glaswegians in municipal activity is almost proverbial. One of their most recent innovations is the provision of a series of lectures, to be given during the winter months, arranged by the Corporation, and which are to be descriptive of Corporation schemes and work, and which are to be delivered by the heads of Corporation departments. The first lecture was delivered by the treasurer of the water department on November 10th on "Glasgow's Water Supply." Mr. Chamin, the City Electrical Engineer, has lectured on "The Municipal Electric System," and Mr. McColl, the well-known superintendent of cleansing, on "How the City is Cleaned." Whilst other lectures in the course are "Subterranean

Glasgow; or, How the Sewage Reaches the Sea," by Mr. McDonald, the City Engineer; and "The Gas Supply," by Mr. Foulis, the City Gas Engineer. The idea of inducing her citizens to interest themselves in their own government, property, and privileges, is, it appears to me, an eminently good one, and worthy of imitation. Glasgow Councillors are proud of their attainments, and they have reason to be so.

I REFERRED last week to the rapid strides which are being made in the development of lighting by acetylene. My remarks appear to have excited considerable interest, for I have been asked by several readers if I would give some particulars as to the manufacture of the gas. Briefly, I may explain that acetylene is manufactured from calcium carbide, and the latter is a compound of carbon and lime which are mixed together in a finely-ground state, the two substances being fused together in an electric furnace at a very high temperature and converted into calcium carbide, which is then allowed to cool and broken into sizes suitable for distribution and sale. The carbon required for the process is obtained from anthracite coal and coke. Both carbon and lime are comparatively cheap, but the use of the electric furnace is costly, as the horse-power required in connection with it is very great. For this reason, carbide can only be manufactured economically by means of cheap water power, and at the present time all carbide factories are located near waterfalls, and the only one I believe in Great Britain is that belonging to the Acetylene Illuminating Company at the Fall of Foyers, in Scotland, where about 3000 horse-power is utilised.

CARBIDE of Calcium is of two kinds, "ingot" and "run" carbide, the latter being the kind manufactured at Foyers. Each pound of carbide as sold is supposed to yield not less than 5 cubic feet of gas, and the cost per ton is about £16. To obtain generation of gas for portable lamps a special preparation of calcium carbide treated to render it impervious to atmospheric moisture is used, and all that has to be done in this case is to immerse the carbide in water when gas is evolved. As soon as it is withdrawn from water no more gas is evolved, and the carbide in this form remains intact until again immersed. Such lamps are under perfect control, and the moment the tap is turned off generation ceases.

IN installations for villages and institutions the apparatus consists of a generator, usually containing water, into which the carbide is placed, a gasholder and purifier. The whole plant is comparatively simple, is easily manipulated, and there is little danger now attendant in its use. SENEX.

AT the last Torquay Town Council meeting the Town Clerk, and the waterworks engineer, reporting on the question of supplying Teignmouth with water, stated that the supply asked for might be granted, provided the District Council would enter into a formal agreement to take water for thirty years on terms that were stated. The Water Committee recommended that an offer be made to supply Teignmouth with a minimum of 15 million gallons, and a maximum of 25 millions per annum, delivered by meter into a 7in. main, to be laid by the Teignmouth Council for fifteen years at a charge of 1s. 1d. per 1000 gallons, provided that the quantity supplied in any one day shall not exceed 200,000 gallons. In the event of this offer being accepted by Teignmouth, the Town Council will take steps to raise the dam of the Kennick reservoir seven feet, at a cost of £12,000.

National Health Society.

OFFICIAL TRANSACTIONS.

ASSOCIATION OF NATIONAL HEALTH WORKERS.

A GENERAL meeting of the Association was held at 53, Berners-street, at 3 p.m. on Saturday, December 29th. Miss Christine Hall was appointed hon. secretary and hon. treasurer, and Miss Pridham and Miss Draper were elected members of the Committee. A resolution was proposed by Dr. Childs and seconded by Miss Baker to the effect that at meetings of the Executive Committee three members should constitute a quorum, and that nine members should be a quorum at general meetings. After the meeting a paper on "Infant Life Protection" was read by Miss Smith, County Council Inspector under the Infant Life Protection Act, the chair being taken by Dr. Childs in the unavoidable absence of Lady Priestly, who was prevented by illness from being present. There was a good attendance, and an animated discussion followed the lecture, in which Mrs. Westaway, Mrs. Greenwood, Miss Morgan, Miss Allen and Miss Baker took part.

ABOUT fifty guests responded to the invitation of the president, Dr. Childs, and the Committee to the conversazione on the evening of the 29th. Dr. Spitta, aided by his son, kindly supplied the chief entertainment of the evening. By means of a splendid lantern he demonstrated some of the choicest and most recent marvels of micro-photography. Amongst the most interesting slides were the eye of the beetle, showing the thousands of miniature "eyelets" of which it is composed, and, wonderful to relate, a corresponding number of portraits of the demonstrator, each taken through and focussed by an individual "eyelet"; also a transverse section of the retina of the human eye showing distinctly the "rods and cons." Various bacteria and other microscopic parasites were also shown, including the notorious plasmodium malariæ, the cause of malaria. This organism was shown in the various stages in which it invades and develops both in human blood and in the body of the mosquito, which is now very generally regarded as the vehicle of the infectious parasite, the plasmodium. The lantern display was followed by a short and much appreciated musical programme, in which Miss Lydia Lévy, Miss Katherine Martin, and Miss Lillian Hall took part. Miss Lankester received the guests.

CORRESPONDENCE.

(*To the Editor of* THE SANITARY RECORD.)

A CLEAN BILL OF HEALTH.

SIR,—It is an interesting and, I believe, a rare fact for an urban district to be entirely free of infectious disease for a twelvemonth. The past year has given this immunity to the North Wales health resort of Penmaenmawr, and it is all the more noteworthy when coupled with the fact that there was a larger visiting population than in any previous year. The total absence of zymotic mortality here in 1899 directed attention to a remarkably clean bill of health; and much satisfaction is felt locally in having improved upon even that good record. It would be information to know if any of your numerous readers can of their experience or knowledge relate a like condition elsewhere. The resident population here is about 3500, and the Notification Act was adopted soon after it became law.—Yours faithfully, ERNEST WORRALL.

Penmaenmawr, New Year's Day, 1901.

THE EVOLUTION OF THE JERRY-BUILT HOUSE.

In the current issue of *Public Health* Dr. E. Gwyn, Medical Officer of Health for Hampstead, deals with "The Jerry Builder Considered in Relation to the Housing of the Poor." According to Dr. Gwyn the evolution of the jerry-built house appears to be somewhat as follows:—Some green fields, or some mansion with a few acres of pleasure or garden ground, conveniently situated in the suburbs, are advertised to be sold, or let on building leases. Timber is forthwith cut down, roads formed, and sewers built; plans are prepared by which the ground is cut up into plots containing a feet of frontage and a greater number of feet for depth. These plots, if not sold, are let at a ground rent of so many pounds each, the lessee undertaking to put a house of specified value upon it. By these means it is intended that a field, which at the time of letting brings in a few shillings per annum as grazing ground, shall, when covered with houses, bring in as many pounds, and that, moreover, the houses erected thereon shall revert to the ground landlord at the termination of the lease. But to get the houses built something more is needed. The capitalist, often the owner of the land, now comes forward with loans, to enable a class of small builders to undertake the work. These builders, for the most part men with little or no means, but with a certain knowledge and experience, have to build the houses and to support themselves and families during the period in which the loans can be made to last. A surveyor is appointed to protect the advancer of loans, and if he prove faithful to his employer the brick, lime, and timber merchants, and others, will probably suffer by the bankruptcy of the builder. But if the builder is not to fail, it follows that he must go to the cheapest market for his materials. His bricks will be porous, his timber "shaky," his mortar deficient in lime, his plaster destitute of hair, his woodwork and joinery of the most unsatisfactory kind, and his sanitary appliances of the cheapest quality. The drainage, supposed for the most part to have been supervised by the sanitary officials, will often be found to be defective, and although the introduction during the last few years of the water test has recently secured an improvement in this respect, it may be said, without much fear of contradiction, that in a great part of London the jerry builder has been content with clay-jointed drains, which are now leaky.

The houses thus erected will, if possible, be sold, often at a very small margin of profit, in order to obtain a quick return of capital, with a view to further operations, or, failing sale, will be let at a cheap rate to start them. As a result, whatever may have happened to the builder, at least the grand object of the whole transaction, namely, the creation of a valuable ground rent, will have been obtained. It not infrequently happens that an artisan or clerk will be tempted to invest his savings in one of these houses, either for his own occupation or for letting, it may be, by the aid of one or other of the benevolent or building societies. He too often finds, either on the occurrence of illness or upon complaint from a tenant, that after the visit of the Sanitary Inspector he is addled with the costs of re-drainage—a veritable fine, in fact, of £40 or £50, which he is quite unable to meet.

It is said that Madame de Pompadour exclaimed, *Après nous de déluge.* Well might the jerry builder repeat the remark—a deluge, truly, of sanitary notices from the Authorities to repair the original defects in drainage, obviate dampness, &c. More than 50,000 notices for repair to drains and other sanitary matters are annually served for the abatement of nuisances due in a great measure to original defective construction.

A HINT TO SANITARY ASSOCIATIONS.

In regard to Sanitary Associations, of which there are several in existence, the Glasgow *Sanitary Journal* presses the opinion that there is a distinct opening for an Association that will, metaphorically speaking, push its wares. How many citizens, for instance, it asks, "know what the West of Scotland Sanitary Association is, and what are its objects? Why not canvas for orders instead of waiting for orders to come? It is a fundamental principle in business that a new line of business must, in order to succeed, push for all it is worth." These remarks are followed by some capital advice addressed primarily to the association referred to, but sufficiently interesting to be reproduced for the benefit of others. "Let a circular be issued describing in brief the beneficial objects of the Association, and at the end of the circular the information added that for '(say) 5s. a year we shall undertake to test your drains when called upon to do so, or at least once a year. Our Mr. So-so will call upon you in a fortnight to receive your answer, &c.,' or words to that effect. Residents in tenement properties should jump at such an offer, and if the association is willing to undertake the work that will undoubtedly wax into magnitude, much good will result. Indeed, the Public Health Authorities in a few years would remark upon the marvellous decline in infectious diseases. At first blush one is apt to run away with the idea that the association and the statutory Sanitary Inspector will come into conflict. But closer inspection will show that the Sanitary Inspector only interferes when he suspects, or is aware of, the existence of a nuisance. Smoke or other testing by an association would be applied to discover defects. In fact, the association would, in process of time, prove itself to be the Sanitary Inspector's most powerful ally in doing good."

SOAPS: GOOD AND BAD.

By Jerome Walker, M.D.

Soap is one of the most important necessities of modern life. Properly made and properly used, it is a detergent or cleanser, a deodoriser, a disinfectant, and an antiseptic. Improperly made, it is an irritant when applied to the human skin, and if it contains dirty and decomposing fat is a filthy application. It is well recognised by physicians that eruptions on the skin persist and recur with the use of particular kinds of soap. This cannot be wondered at when "spiculæ of bone, pus cells, and fragments of connecting tissue" have been found in certain soaps. Soap fat, or the fat which forms an essential ingredient of soap, by some soap makers and many collectors of it, means any sort of grease. Too often the fat used in soap making is putrefying kitchen refuse, fit perhaps for axle grease, but not for the human skin.

In an article in a recent number of the *Medical News*, entitled "What is the Best Soap to Use in Washing the Scalp?" the author rightly says "many women who make their living by caring for the hair have some mysterious soap which they use, vaunt, and try to sell to their customers, but the composition of which they will not reveal." He then adds, "As a matter of fact, except in a very few conditions of the scalp, it makes little difference what sort of soap is used provided it is made by a good manufacturer." But it does matter very much what sort of soap is used. It is the good soap we want, whatever the character of the manufacturer may be.

Unfortunately the statements of the manufacturers of soap, as well as of other articles, as to the purity and usefulness of the products of their factories, are too frequently unreliable. Such statements made, it may

be, by men considered good, are looked upon as clever. Soaps are in reality salts, stearates, palmitates, and oleates, chemical compounds of water, and fatty acids evolved in the disintegration of fat by heat, with soluble alkalies such as soda, potassa, or borax. Good soap is made of pure and carefully compounded ingredients. There is no decomposed fat, and all, or nearly all, of the fat or oil used is saponified, with no excess of alkali. Soaps attack dirt and render it soluble in water mainly by alkalinity. But there should be irritation of the skin by their use. There should be just enough water to render the soap readily soluble, and no more. There is no admixture of foreign matter, such as talcum, clay, &c., which is commonly present in the cheap toilet soaps. A good soap also has a uniform and permanent colour, and no disagreeable odour. It is not sticky, and when used upon the skin, leaves it clean and soft.

The softness of soap depends to a considerable extent upon the amount of oil in the fat used, but potash soaps are usually softer than soda soaps.

The best toilet and medicinal soaps are made from vegetable oils or fresh fish oils. Their perfuming and colouring require great skill. Perfumes and colouring matter, if not carefully incorporated in soaps, may detract from their detergent properties. It is also a question whether in some of the medicinal soaps, *i.e.*, soaps to which are added medicinal substances for external medicament, the detergent power is not impaired. A pure soap, even without any medicinal substance added, answers well oftentimes as a disinfectant, deodoriser, and antiseptic, though its cleaning powers alone recommend it to most persons.

Borax soap and pure toilet soaps only should be used for infants and children, or adults with delicate skins.

Finally, when we consider that soap is a necessity of modern life, for the laundry, the toilet, as a vehicle for medicinal applications, and for physicians and surgeons in the exercise of their functions, it is especially important that the soap used should be pure, and that the name of the manufacturer should be a synonym for honest goods.—*The Sanitarian.*

THE SMOKE NUISANCE IN CANADIAN CITIES.

Toronto has just completed a costly new city hall, and as it is becoming discoloured by the smoke of a large industrial establishment in its immediate neighbourhood, the City Council has taken up the question of compelling all manufacturers to consume their own smoke. Some twenty years ago Professor Carpenter, the eminent physiologist, visited Toronto, and was then very much surprised that a city of such beauty and such salubrity of climate should be befouled and have the health of its citizens jeopardised by the ever pouring out of these clouds of black smoke from the tall chimneys of the great manufactories of the city. Montreal suffers greatly from the same nuisance, and it is understood that the city fathers of that metropolis are to follow the lead of Toronto in maintaining a purer atmosphere for its citizens. Cape Breton is a part of Canada which is now passing through a period of great development through the energy of the well-known Boston capitalist, Mr. Henry M. Whitney. This gentleman believes that the best way of dealing with this smoke nuisance in a satisfactory manner is to provide smokeles fuel, which he is now doing on a large scale for the city of Boston. He has erected 400 by-product coke ovens in which the coal of Cape Breton is converted into a cheap smokeless fuel. He states that the gas, tar, and ammonia which are saved more than pay for the trouble of converting the coal into coke. When this fact becomes to be generally recognised in Canada, its cities and towns will produce a purer atmosphere for their inhabitants.

REVIEWS.

Theory of Engineering Construction: a Reference Book for Engineers and Students. By Ernest H. Essex, Assoc. M. Inst. C.E. 216 pp. Price 5s. London: The St. Bride's Press, Limited.

This book is really a selection of notes and formulæ on the theory of construction, arranged in the form of answers to the questions set at examinations for the election of associate members of the Institution of Civil Engineers, and embrace answers to fifty-one questions in theoretical and elementary applied mechanics, theory of structures, strength and elasticity of materials, and geodesy. The answers are illustrated by diagrams, and appear to us to have been well and carefully done, and with a preciseness which is commendable. A short syllabus of the subjects of the examination is given. Intending candidates for the examination will find the book of very considerable service. The volume is nicely printed and well got up,

The Law and Practice of Rating both Within and Without the Metropolis. By Walter C. Ryde, of the Inner Temple, Barrister-at-Law. Large 8vo. 756 pages. Price 35s. Shaw and Sons.

For parochial officers, valuers, and lawyers engaged in the practical administration of the rating law there is no book which surpasses or equals the one before us. The book is divided into four parts, Part I. being concerned with the persons liable to be rated, Part II. deals with the measure of liability, Part III. with the different kinds of property, and Part IV. with the practice and procedure outside and within the metropolis. The whole subject is discussed in a thoroughly exhaustive manner, and with a freshness which is exceptional and pleasing, and makes the book of especial value to laymen, such as Assistant Overseers and members of Assessment Committees. It is impossible to peruse the book without being struck with the extreme care which has been exercised by the author in compiling notes of all cases which bear directly or indirectly on the subjects to which the volume is devoted, and numerous cases are reported which we do not appear to have observed elsewhere. This volume will rank as the standard book on the law of rating.

AN INDICTMENT OF SEWER VENTILATION.

An article in the evening *Sun* by Mr. William Brown, with the somewhat sensational heading, "The Public Health Service: Its Disastrous Breakdowns and How to Prevent Them," has come under our notice. We had anticipated some "revelations," but, like the patent medicine advertisements, we only reach the real question at issue, from the writer's point of view, towards the end of the article. In Mr. Brown's opinion, the cause of the periodical failure of our system of sanitary defence is all the result of an error of opinion on an apparently small point. Our street sewers, when properly laid, and provided with openings at intervals for the admission of fresh air, are described as clean running and ventilated, and are assumed to be free from danger to the public. "This," says Mr. Brown, "is false and fatal assumption. Although the sewers may be quite clean running, under the atmospheric conditions just referred to, they cease to be 'ventilated.' The gases of putrefaction then accumulate in the sewers, making the sewer air increasingly foul. This foul air must, by the nature of things, be largely got rid of by the ventilating openings, and, especially if the weather is close and muggy at the time of expulsion, the air which the people have to breathe becomes thereby so deprived of oxidising power that healthy bodily processes cannot be kept up, and the

population soon begins to show the bad effects of this weak air in its vital statistics, the injury to health being in proportion to the continuance of the adverse conditions.

Moreover, it is more frequently the case than is generally supposed, that there is a direct entry of this polluted sewer air into the houses by the house drains. Trapped connections cannot be absolutely relied upon to prevent this entry, and this element of uncertainty applies to the houses of the rich as well as to the poor.

Recognising the position just described, a remedy has been sought by some in a system of high ventilating shafts. The public sense has never favoured this system, and with only too good reason. As has been demonstrated in the technical Press, this system is not only costly and unsightly, but it actually accentuates the evil it is intended to cure. Refutation of this demonstration has been publicly challenged in very pointed terms by a leading technical journal without evoking any reply from those responsible for the adoption and continued use of the system.

Now, seeing that so much of the failure in our sanitary practice is owing to the formation of foul sewer air, it is obvious that the remedy must be sought in some practical means of preventing the air in sewers from ever becoming foul, that is not only under those atmospheric conditions when the means for natural ventilation will prove effective, but also during those changes when natural ventilation must fail. And there is such a means."

STREET REFUSE IN THE CITY OF LONDON.

The Corporation have for some time past been considering the question of dealing with dust and refuse from the City, and, among other things, the practicability of generating electricity from steam raised by burning the refuse. Mr. D. I. Ross, the City Engineer, reporting to them on the subject, states that last year 74,621 loads of refuse were removed from the City to Lett's Wharf, Lambeth, near Blackfriars Bridge, the lease of which expires in 1909. About 60 per cent. of the house and trade refuse is cremated, but the street sweepings, slop, and market refuse are shot into barges and removed daily. The Corporation, having permitted two electric lighting companies to obtain powers to supply electricity for lighting and other purposes, could only generate electricity for their own purposes or for street lighting. They were in a totally different position to other Local Authorities who are supplying electricity in their various districts, and who are cremating their refuse and utilising the power generated therefrom in connection with their electricity works. It was extremely doubtful whether the house and trade refuse could be profitably dealt with by cremation, as it consisted principally of paper, straw, and packing materials of very little calorific value, exceedingly bulky and difficult to manipulate. Although from a sanitary point of view cremation was preferable to any other mode of dealing with the refuse, mature consideration leads Mr. Ross to believe that, having regard to the difficulties of obtaining a suitable site in the City, and the expense thereby entailed, and to the difficulties that would arise in working any apparatus that might be erected without being stopped by legal proceedings, the objections to this course were almost insuperable, and in his opinion it would be better to barge the refuse direct into the country from the City than deal with it there. Mr. A. A. Voysey, the Electrical Engineer of the City, has also made an interesting report to the Corporation on the subject. The Streets Committee, on these reports, have advised the Corporation to barge the dust and refuse into the country, and to obtain some suitable site for the purpose. The question will be decided on the re-assembling of the Corporation after the vacation.

Public Works.

SEWERAGE.

The Local Government Board has at last sanctioned a loan by the Castle Donington Rural District Council of £1680, for the purpose of completing the sewerage and drainage scheme.

The Kingswood Urban District Council's seal has been affixed to the memorandum of agreement with Mr. William Robson for the purchase of land at Cowhorn Hill, Oldland, as a site for the drainage outfall works.

The Finance Committee reports to the Colchester Town Council that it has no objection to the proposals of the Roads and Drainage Committee to borrow £10,000 for the extension of the sewerage outfall works, and a further sum of £9000 for the construction of new main sewers for the sewerage of St. Botolph's Valley and Maldon-road districts.

The Sewerage Committee of West Bromwich Corporation report having considered an exhaustive report of the Borough Surveyor (Mr. A. D. Greatorex) on the bacterial treatment of sewage, and recommend the Council to adopt the scheme set out in the report for dealing with the sewage of the borough, and make application to borrow £15,000 for carrying out the scheme.

At a special meeting of Linlithgow Burgh Commissioners last week the deed of agreement between Mr. Hamilton, West Port, and the Commissioners for the lease of ground for the erection of sewage works for the town on the principle of the septic tank was submitted and revised. A plan of the works was also submitted, and after perusal the meeting authorised the Provost and Bailies Dowie and Beattie to execute the deed on behalf of the Commissioners.

The Derby Corporation intends promoting a Bill during the ensuing session the object of which, among others, will be to extend the boundaries of the borough and to empower the Corporation to construct tramways, additional waterworks, and sewage disposal works, and to effect certain street widenings and improvements. The following borrowing powers are sought by the Corporation:—For tramway purposes, £241,535; for waterworks purposes, £50,962; for sewerage and sewage disposal purposes, £290,000; for street improvements, £24,570; for crematorium, £2500; for conversion of existing closet accommodation into water-carriage system, such sum as may be required; for technical college, £6000; and sums required for compensation purposes and the costs of the Act.

The Special Sub-committee of the Birkenhead Town Council appointed to consider the question of sewer ventilation just recently presented its report. It showed that the fullest consideration had been given to the matter, and the Committee was of opinion that the sewers of the town should be ventilated. It recommended that the ventilation should be provided by up-cast ventilators instead of by surface gratings, and that the necessary alteration be proceeded with in all streets of 30ft. in width and under as soon as practicable. In submitting the report to the Council, Alderman Singleton said that in the narrow confined streets the escape of sewer gas from the surface gratings was very dangerous, but in the other streets it was not so bad. They meant to erect ventilators where they could, provided they got permission. Hitherto they had little difficulty in getting the owners' consent to erect ventilators. They had had many complaints of the surface gratings, and he believed that he was correct in saying that 50 per cent. of the owners had promised. The report was approved.

THE Local Government Board has refused the application of the Skegness Urban District Council for sanction to borrow £1360 for the improvement of the sewage works, on the ground that the arrangements are quite inadequate to deal efficiently with the sewage taken to the outfall.

AT a recent meeting of the Billesdon District Council the Clerk read a letter from the Local Government Board stating that the Board could not advise the Rural District Council as to whether or not it should proceed with the sewerage and water schemes referred to in Mr. Everard's report, and pointing out that the duty of providing each contributory place within the rural district with an effectual drainage and a proper supply of water had been placed upon the Rural District Council and not upon the parish meeting, and that the responsibility, therefore, attached to the Council would not be affected by the attitude of the parishioners. If the Rural District Council adopted schemes of water supply and sewerage and sewage disposal, and applied to the Board for sanction to loans to defray the cost the Board would be prepared to consider the application, and would probably direct the holding of a local inquiry before coming to a decision. Mr. Sharpe said it was generally admitted that something would have to be done in the matter of sewerage, and on this motion, which was seconded, it was decided that some sort of scheme should be adopted, and that the Committee should confer with Mr. Everard as to the cheapest manner of providing a proper scheme.

A FURTHER step, and one which it is hoped will mark the completion of the work of establishing a thorough system of drainage and sewage disposal for the borough of Shrewsbury, was taken last week, when the Mayoress, in the presence of a large and representative company, formally opened the door of the new pumping station at the sewerage works in Coleham and set the machinery in motion. The engineers of the scheme, which is now nearing completion, are Messrs. John Taylor, Sons, and Santo Crimp, of Westminster. The scheme, which is known as the main drainage works, was begun about four years ago. It comprises a complete system of sewers for intercepting the sewage, which at present discharges into the Severn. The sewage for the most part is conveyed to the pumping station by large iron sewers; at the pumping station it is pumped by means of a pair of compound beam-pumping engines into a gravitation sewer of brick, about a mile and a-half in length. From this it is discharged on to the land purchased by the Corporation at Monkmoor. There it will clarify, the solids will be pressed into innocuous cakes of manure, and the inoffensive liquid will be spread over the land. It is not claimed by the engineers that they are introducing into the works anything of an unusual character; they have worked on old-fashioned principles, modernised and brought up to date as regards details. The cost of the scheme is not at present known, but it will probably come near £100,000, of which about £22,000 represents the purchase money of the land.

WATER.

AT a recent meeting of the Pershore District Council, Mr. Caink, the Worcester City Engineer, wrote that with regard to the proposal to supply Pershore with water from Worcester, there were no engineering difficulties in the way. The city of Worcester would deliver water to the city boundary at 9d. per thousand gallons, and he suggested that a reservoir should be constructed at Allesborough Hill holding about 250,000 gallons for the supply of Pershore. The proposed works were estimated to cost £8864, and these works would include the cost of snpplying Whittington and also a supply for Pinvin. The estimate was referred to a Committee.

LYDFORD village new water supply works have been passed by Mr. Bellamy, C.E., and there are now hopes that Lydford will steadily develop as a moorland holiday resort. The castle ruins and the waterfall and gorge on the one side, and Dartmoor, with its dales, rivers, and tors, on the other, are permanent attractions. Several new residences are to be built forthwith.

AT the last meeting of the Menston Parish Council, the chairman reported that the Menston Waterworks Company claimed £20,000 as the price of their works, and that they had appointed Mr. Gott as their arbitrator, and Mr. Woodhead was to be their principal witness. It was stated that the Wharfedale Rural District Council, which is purchasing the works, has appointed Mr. Fawcett as its arbitrator, and Mr. Silcox will be the principal witness.

A SPECIAL meeting of the Wolverhampton Town Council was held in the Council Chamber, last week, "to take into consideration, and determine upon, the expediency of promoting, in the next session of Parliament" a new Bill "to authorise the Corporation to construct additional waterworks, and to raise further money for the purposes of their water undertaking, to extend its limits for the supply of water, and to make further provisions in regard to the water undertaking of the Corporation and other purposes." Among the provisions of the proposed Bill were provisions for borrowing a sum of £39,740 in addition to the amount already borrowed.

IN view of the provisional order which the Corporation of Irvine is promoting in Parliament for power to acquire an additional catchment area for the waterworks, deputations from the Burgh Commissioners of Saltcoats, Stevenston Sub-committee of the County Council, Joint-committee for Kilwinning Water Supply District, and Nobel's Dynamite Company met the Corporation of Irvine last week. All these places derive their supplies from the Irvine reservoir. Objection was taken to the order on the ground that no provision was made in the agreement with the authorities to substitute a different supply; that Irvine was not entitled to draft on to the Burgh Act of 1881 new provisions for which parliamentary powers are necessary, nor to subject to outside local authorities outside the agreement. Mr. James Campbell, solicitor, Saltcoats, appeared for the outside authorities, and spoke at length. He referred to the priority clause in the Act of 1881 as being the principal bone of contention. If that clause was not deleted the outside authorities would oppose the order. Provost Murchland replied to the objections, and the deputations withdrew.

THE Salford Corporation Bill, which has been deposited for next session, deals exclusively with the future water supply to that borough. The preamble, which covers five pages of the Bill, sets out the circumstances and parliamentary enactments under which the Corporation become entitled to a supply of water in bulk from the Manchester Corporation up to a limit "not exceeding 2,000,000 gallons a day at a price not exceeding 3d. per 1000 gallons, as an arbitrator to be appointed by the Board of Trade should appoint." The operative clause in the Bill, carrying out the recitals of the preamble, proposes to enact that the Corporation, by giving three months' notice, may require the Manchester Corporation to supply to Salford "such daily quantity of water over and above the daily quantity of 2,000,000 gallons as the Corporation in such notice state that they require for the township of Salford." The remaining clauses in the Bill empower the two corporations to borrow "such sums as may be necessary, and as the Local Government Board may sanction" for carrying into execution any agreements that may be entered into under this Act, provided that the aggregate amount which may be borrowed shall not exceed £50,000.

The Waterworks Committee recently reported to the Lincoln County Council that the Local Government Board had sanctioned the borrowing of £13,500 for ten years for boring for water, with a promise to extend the time for repayment if the works prove successful, and the Committee had instructed their engineer to invite tenders. The Board deferred consideration of the application to borrow a further £2500 for sinking the well until the boring works have been completed. The Chairman of the Committee stated that they were not now taking water from the river Witham, so there need be no anxiety about the drinking water being polluted by the sewage effluent from Bracebridge County Asylum which was discharged into the river. The discoloration of the drinking water had been caused by the recent heavy rains, and the Committee were now enlarging their filter beds.

At a recent meeting of the Grays Urban Council a letter was read from Romford Urban Council inviting delegates to meet an Executive Committee of Council concerned to discuss the question of the heavy costs and charges in connection with the recent Water Trust proceedings. The Chairman said the Executive Committee satisfied themselves that the charges of Parliamentary agents, which appeared to be those which were strongly objected to in certain quarters, were exceedingly moderate. The total amount of the Bill, for the proceedings at both parliamentary sessions, was £18,000. The Romford Council was apparently now desirous of going behind the backs of the Executive Committee, and to have it all thrashed out by other persons who had not been in close and intimate touch with the whole of the proceedings, as had those who had given a great deal of time and attention to the whole of the work from beginning to end. Mr. E. W. Brooks moved that the Clerk should reply stating that the Council did not see its way clear to do as requested by Romford. The Chairman said in round figures the capitalised value of the concession obtained was certainly from £130,000 to £140,000 over the districts on the present values, and it had cost the districts less than £20,000 to get them. Mr. E. W. Brooks' form of reply was agreed to.

LIGHTING.

A Local Government Board inquiry was held at Ripon last week into the application of the Town Council for sanction to a loan of £7000 for extension to the gasworks.

At a recent meeting of the Electricity Committee of the Bradford Corporation, it was resolved that the consideration of the charges to the Tramways Committee for the supply of electricity should be deferred until the end of the financial year in March.

The Felixstowe District Council has adopted the recommendation of the General Purposes Committee, that Sir William Preece be asked to report to the Council the best course, in the interest of the ratepayers, to adopt with respect to the Council's Electric Lighting Order. Sir William Preece's fee will be fifty guineas.

The Bill to confer further powers upon the Chester United Gas Company has been duly deposited for next session in the Private Bill-office of the House of Commons. By this Bill the company seek powers to acquire additional lands adjoining their existing works "for the manufacture and storage of gas and of residual products." These lands, which must be acquired within the next three years, cover an area of 11,432 square yards, but by agreement the company ask for power to purchase a further five acres, upon which, however, the manufacture of gas and residual products is prohibited.

The Dover Gas Company directors have convened a meeting of their shareholders to confirm their authority to apply to Parliament for the powers which are necessary to extend their works to meet the growing necessities of the town.

A deputation attended the last meeting of the Blaydon Urban District Council asking the Council not to oppose the application which would shortly be made by the Newcastle Electric Light Company for a licence for the extension of power, so that they could supply Blaydon and Royton if necessary. The Council, however, before coming to any decision on the matter wished to be supplied with details by the company.

The Town Clerk recently intimated to the Dublin Council that notice had been given on behalf of the Blackrock Urban District Council of the intention of that body to apply for a Provisional Order authorising it to produce, store, supply, sell, and distribute electricity for public and private purposes within its district. The Town Clerk and Law Agent were directed to take the necessary steps to protect the interests of the Corporation.

Mr. W. A. Ducat held an inquiry on behalf of the Local Government Board at West Bromwich last Friday into the application made by the Town Council for sanction to borrow £5524 for the purposes of their gas undertaking. It was explained by Mr. Caddick, Town Clerk, that the application was brought about by the the rapid increase in the demand for gas during the past few years. The Council proposed to spend £5524 in the construction of a new siding and a bridge over the canal and also in laying down additional plant. The Inspector afterwards visited the gasworks.

One of the Liverpool papers, devoted to the supervision of the gas world in its various bearings, mentions that Dr. Ludwig Mond, of Messrs. Brunner and Mond, has invented a process for the production of fuel gas from a cheap form of bituminous coal or slack, and that a Bill will be introduced into the next session for supplying a large district of the Midlands with the new agent. The price will not exceed, and may even be less than, 3d. and 4d. per 1000ft., according to the quantity taken per quarter; but in any circumstances 4d. is to be the maximum price. The gas will be called, after its inventor, the Mond gas, and it seems that the area in the Midlands to be thus supplied under the Bill is very large.

The lighting of Bognor was discussed last week at a meeting of the Urban Council. An offer was made by the gas company, as an experiment, to fit up a dozen lamps with incandescent burners in the principal thoroughfares, to bear the expenses of up-keep, including lighting and extinguishing, for six months, the Council to pay for the gas consumed, and at the end of that period take over the lamps and burners at net cost if satisfied with the results. The present lamps were said to be of 15 candle-power, but only a 10 candle-power illumination could be obtained; and the new lights were of 80 candle-power, and would cost only about £24. The Council decided to accept the offer, excepting the clause binding it to take the lights over should they be satisfactory.

GENERAL.

The Paddington Borough Council is to be asked at its next meeting to appoint a committee to devise some improvements of the workmen's dwellings within the borough, particularly those near the dustyards.

Having failed, and properly so, to obtain any suitable applications for the position of Ham Green Hospital Medical Officer, at a salary of £100 per year, the Bristol City Council has resolved to issue a further advertisement offering a salary not exceeding £200 per annum.

A Northampton patient has died from whooping-cough at the age of seventy-seven.

The Taunton Town Council contemplate establishing a Horsfall refuse destructor for the borough.

The Islington Borough Council has expressed its approval of the housing scheme of the London County Council at Wedmore-street, Upper Holloway.

The Marsden Urban District Council, when it has received the sanction of the Local Government Board to the loan, will require a new steam road roller and scarifier.

The original office of *Household Words*, in which Dickens made the acquaintance of Mr. John Hollingshead and many other celebrities, is doomed to destruction under the Holborn-Strand scheme.

A Local Government Board inquiry was held last week at Bury into the Corporation's application to borrow £15,000 for market undertakings, and £20,000 for slaughter-houses, refrigerators, ice-making apparatus, &c.

A Local Government Board inquiry has been held at Croydon by Colonel Durnford, R.E., with reference to the application of the Croydon County Council to borrow £2250 for kerbing and paving in North End, and £520 for a new sewer at South Norwood.

The Kingston-upon-Hull Corporation Bill, which has been deposited in the Private Bill-office of the House of Commons, will enable the Corporation to raise for the execution of street works, £560,000; for the construction of the new bridge, £36,000; for tramways, £27,000; and for purchase of land at Cottingham and waterworks, £33,000.

The Colchester Town Council has had before it a scheme for the extension of the sewerage outfall works, the construction of filter beds, the provision of additional sludge plant, and the construction of new main sewers in the St. Botolph's Valley and Malden-road districts, the estimated total cost being £19,000. The discussion on the subject was adjourned for a month.

At the last monthly meeting of the Elland District Council it was decided to invite tenders for the erection of a refuse destructor at the sewage works. A letter was read from the Halifax Rural District Council asking the Elland Council on what terms it would take into its sewers and treat the sewage from the houses at Fixby. It was resolved that the Rural Council be informed that at present the Elland Council could not comply with the request. The Clerk was instructed to advertise for tenders for the erection of public baths, as soon as the sanction of the Local Government Board was obtained.

Giving evidence at a Local Government Board inquiry last week, the Town Clerk of Liverpool told of what the City Council was doing to improve the condition of the people. One hundred and eighty-two houses, with recreation grounds, were in course of erection by the Corporation in Dryden-street and Rachael-street. The money for these houses was sanctioned in three portions by the Local Government Board. On July 25th, 1899, £13,500; on November 8th, 1899, £13,100; and on May 12th, 1900, sanction was given for the borrowing of £1400 for the supply of hot water. There had also been the sum of £30,000 sanctioned within the last few days for erecting ninety-five houses in the Kempston-street area and the Fontenoy-street area, and there was an application now before the Board by the Council for permission to borrow £53,500 to build 208 houses in Kew-street and Newsham-street, in Clive-street and Shelley-street, and in Arley-street. The Corporation also acquired some land under the 16th presentment in Adlington-street and neighbourhood which would provide for 221 houses. They had also acquired in Gildart's-gardens a site for the erection of 137 houses, bringing the total up to 843.

The Leighton Buzzard District Council has decided to make application to the Local Government Board for sanction to borrow £1500 for purposes of town improvement.

A tender for the erection of two underground conveniences on the Grand Parade, Eastbourne, for the sum of £2827, by Messrs. Finch and Co., is recommended to the Eastbourne Town Council for acceptance. This was not the lowest tender.

This is what the local *Star* says of the condition of Montreal:—"Our roads are bad, and it doesn't make a great deal of difference if they should be a little worse. Jolting over them helps the liver. Our parks are beautiful, and it will not add much to our pleasure to have them more so, as it would not be a serious matter if they were a little less so. The lighting of the city is fair. Nobody is going to be a great gainer by having more illumination, or a great loser by getting less of it, but the health of the grown people who pay taxes, the boys and girls who are growing up to be taxed, the toddling babes and the helpless infants; the very life of these depends to a great extent upon the Health Committee's work and the Water Committee's work. Pure water, pure milk, pure food, good drainage, these things come right into our homes, and when our little ones contract fevers from the ill conditions that come from civic neglect, to have to send them away from our homes to lie for weeks in a badly-fitted hospital is too much to ask the citizens to bear."

PERSONAL.

Mr. G. W. Hewes has been appointed Inspector of Nuisances for Burnley.

Mr. H. Jevons, of Swansea, has been appointed Town Clerk for Wigan.

Dr. D. L. Thomas has been appointed Borough Medical Officer for Stepney.

Dr. D. B. Todd has been appointed Public Vaccinator for the rural district of Westbury.

The salary of Dr. Dingle, Medical Officer for Middlesbrough, has been increased to £400 per annum.

Mr. H. W. Longden, of Isleworth, has been appointed Surveyor for the urban district of Penge.

Mr. J. P. Evans has been reappointed Sanitary Inspector for Beeston at a salary of £120 per annum.

Mr. W. F. H. Creben has been appointed Engineering Assistant to the Derwent Valley Water Board, at a salary of £250 a year.

Dr. Broadbent has been appointed Medical Officer for the Newark rural district for the ensuing three years, at a salary of £50 per annum.

The Torquay Town Council has paid the Sanitary Inspector, Mr. Pope, two months' salary, and has decided to dispense with his services.

Mr. M'Caa, Assistant Sanitary Inspector, Perth, has been appointed Sanitary Inspector for the borough of Irvine, at a salary of £100 per annum.

Dr. Brown has been appointed Medical Officer for the Diss district, under the Depwade Board of Guardians, subject to the approval of the Local Government Board.

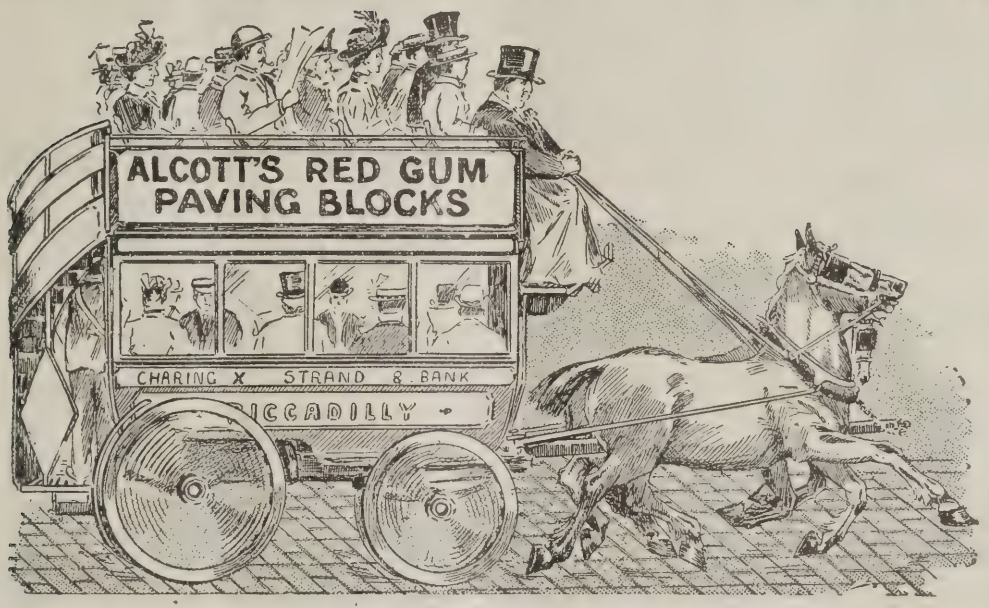
It is stated that the new electrical adviser to the Manchester Corporation is Professor A. B. W. Kennedy, of London. The payment of £15,000 is to be made for his services.

Mr. F. E. P. Edwards, A.R.I.B.A., one of the chief assistants engaged in the City Architect's Department at Liverpool, has been appointed City Architect for Bradford, at a salary of £400 per annum.

Alcott's Red Gum

Is ABSOLUTELY the]

BEST WOOD FOR STREET PAVING.



THE "BUS-HORSE" BRAND.

ALCOTT'S RED GUM is a durable Paving.
ALCOTT'S RED GUM is not Slippery.
ALCOTT'S RED GUM is Noiseless.
ALCOTT'S RED GUM does not Swell nor Shrink.
ALCOTT'S RED GUM wears Smooth and Even.
ALCOTT'S RED GUM does not wear into ruts; does not require gravel; is easily cleansed and, being non-porous, is sanitary.

For Particulars, &c., apply to

EDWARD ALCOTT,

65 and 67, Millbank Street, Westminster,

LONDON, S.W.

THE Local Government Board has sanctioned the re-appointment of Dr. Boustead as Medical Officer for the rural district of Hexham, for one year, at a salary of £210 per annum.

MR. ALFRED MILLS, Assoc. San. Inst., Sanitary Inspector of the Borough of Bethnal Green, has been appointed Building Inspector to the Hornsey Urban District Council.

THE Richmond Medical Officer of Health (Dr. J. P. Rowlands) fell from an omnibus at East Molesey on Saturday week last, and he died on the following Monday morning. He was in his seventieth year, and had been Medical Officer under the Richmond Town Council and its predecessor—the vestry—since 1872.

MR. JOHN BRIGGS, chairman of the Stainland District Council, died suddenly at the railway station, West Vale, Yorkshire, on Saturday last. He was on his way to Halifax to attend the police-court, when in consequence of hurrying he was taken ill, and expired. He was fifty-four years of age, and a Liberal in politics.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2064. — BACTERIAL AND BIOLOGICAL PURIFICATION OF SEWAGE.—"J. B." writes:—"Will you be good enough to describe the difference between bacterial filtration and biological means of purifying sewage?"

Answer.—The terms biological and bacterial purification of sewage are now indiscriminately used to describe the method of purifying sewage by the aid of minute organisms which are present in the sewage itself, and which by the construction of (1) special forms of tanks, or (2) artificial beds or filters termed bacteria beds are cultivated under favourable conditions, so as to secure their activity and agency in converting the solids in sewage into ammonia, hydrogen, &c. Roughly speaking, there are two systems of bacterial or biological purification, viz., (1) the septic tank or Exeter system, where the sewage is run directly into a tank without any preliminary treatment, and where anaërobic organisms act upon the sewage and liquefy the organic solids and prepare it for further treatment in a bacteria bed or beds, where aërobic organisms effect further purification termed oxidation or nitrification; (2) the Sutton or double contact system, where the sewage is run either directly, or after passing through a detritus tank, into two beds, the first termed a coarse-grain bed, constructed of clinker or ballast of a gauge of not less than $\frac{3}{4}$in., the effluent from which is passed upon another bed termed a fine-grain bed composed of coke breeze, ashes, fine ballast, or sand of a gauge of $\frac{3}{16}$in., the effluent being sufficiently pure to discharge into a stream. In both these systems the sewage is locked in the beds for a period of about two hours.

2065.—SANITARY INSPECTOR: WHETHER PRESCRIBED AGE LIMIT FOR RETIREMENT.—"T. S. H." writes:—"Will you advise as to whether there is any age limit at which a Sanitary Inspector shall relinquish his office?"

Answer.—No. There is no limit prescribed either by statute or order in regard to the office of a Sanitary Inspector or other public health official as to the age at which he shall retire.

2066.—BUILDING BYE-LAWS: DISAPPROVAL OF PLANS: NOTICE AS TO.—"Surprise" writes:—"The enclosed plans have been before a certain Urban District Council and disapproved, the only reason for such disapproval being as stated in a letter written by the Surveyor, 'because they do not comply with the bye-laws in force in the district.' I shall be glad if you will give me your opinion (1) As to whether the above letter is a sufficient notice under the Public Health Act, 1875; (2) whether the plans are in accordance with the enclosed bye-laws, which are similar to those in force in the said district; and (3) if the parties would be justified in erecting the building?"

Answer.—(1) The notice referred to is sufficient. Sec. 158 of the Act of 1875, which applies, only prescribes that "the Authority shall signify in writing their approval or disapproval of the intended work," and the Section has been complied with. It is a general practice, however, with Local Authorities to signify in what respect the plans do not comply with the bye-laws, though this is not obligatory. (2) The plans are not in accordance with the bye-laws. There is, *inter alia*, no open space at the rear exclusively belonging to each dwelling, a most important omission, and one which no Local Authority could justify. (3) No. If the owner proceeds with the building the Local Authority may pull down the same and recover the cost of so doing from him, and they may also proceed for penalties for contravening the bye-laws.

J. & M. CRAIG, Ltd., KILMARNOCK

THE VENTILATION OF SEWERS.*

By H. Gilbert Whyatt, A.M.I.C.E., Mem. San. Inst., Borough Engineer, Grimsby.

The law upon the subject.—The Public Health Act, 1875, contains the following section, No. 19:—"Every Local Authority shall cause the sewers belonging to them to be constructed, covered, ventilated, and kept so as not to be a nuisance or injurious to health, and to be properly cleansed and emptied."

It will be seen that this includes not only ventilation, but the keeping of them in such a condition as that they shall "not be a nuisance or injurious to health," and it will be seen, upon full consideration of the question, that the condition of the air in the sewers depends in great measure upon their construction, condition, and cleanliness.

Variation in the flow of sewage.—Previous to the erection of the pumping station in Riby-street, the sewers were tide-locked twice each day, and the sewage was backed up in the sewers by the rising tide, and held there for seven or eight hours out of the twelve. This rising of the tide, of course, forced all the air out of the sewers through such openings as existed, and thus twice each day the whole of the aërial contents of the sewers was forced up into the streets and curtilages of the houses.

Since the opening of the pumping station this action of the tide has been averted, and the pumps, under ordinary circumstances, keep the water down to an average level; but during heavy rain storms the pumps are not able to deal with the whole flow, and, consequently, in times of storm, the air is still forced out in large quantities. This follows the "line of least resistance," and where the sewer manholes are constructed with closed covers the air forces its way through the traps of gullies, &c. In several cases (see Appendix No. 2) the pressure has been so great as to absolutely lift up the manhole cover and frame and surrounding pavement, and carry it a distance of a few yards. The variation between the day and night flow of sewage also always causes a "breathing" or in-and-out movement of the air.

The air in sewers.—The London County Council, in 1893, instructed one of their chemists, Mr. J. Parry Laws, F.I.C., to make investigations into the air in sewers under various conditions and circumstances, and his observations proved that the micro-organisms in the air of sewers are related to the micro-organisms in the external air, and not to those in the sewage itself; and hence, however full the sewage is of disease germs, they do not pass into the air of sewers in the absence of violent splashing, nor yet when considerable air currents prevail in the sewer. Mr. Laws, also by experiment, found that no micro-organisms were disseminated in the sewer air from the walls of a pipe sewer which had been empty for twelve days, and where immense numbers of microbes must have been clinging to the sides.

Many medical scientists have proved to their own satisfaction that sewer air is incapable of disseminating the germs of disease, but it is certain that more diseases are now popularly supposed to be traceable to sewer gases than was the case some years ago. It is almost certain, too, that those who live in houses to which sewer gas has access are much more liable to infection from zymotic diseases than those who live in pure atmosphere; whilst, on the other hand, the men whose work occupies them several hours each day in and about sewers seldom acquire any of these diseases.

Mr. J. Parry Laws admits the injurious effects of sewer gas in a later report, when he says:—"Although one is led almost irresistibly to the conclusion that the organisms found in sewer air probably do not constitute any source of danger, it is impossible to ignore the evidence, though it be only circumstantial, that sewer air in some instances has had some casual relation to zymotic disease. It is quite conceivable, though at present no evidence is forthcoming, that the danger of sewer air causing disease is an indirect one; it may contain some highly poisonous chemical substance, possibly of any alkaloidal nature, which, though present in but minute quantities, may nevertheless produce in conjunction with the large excess of carbonic acid, a profound effect upon the general vitality."

In my opinion, where there are frequent alterations of level in the flow of sewage, and strong currents of air, it is possible for disease germs deposited upon the sides of the sewers to pass into the sewer air through evaporation.

Many municipal engineers and Medical Officers of Health blame the intercepting trap for the increase in the quantity and foulness of sewer air. Some go even so far as to advocate its omission altogether. The chief point raised by them is that the trap is never adequately flushed out, and that decomposable matters remaining in the trap putrefy before they reach the sewer. The smell of fresh sewage is not particularly offensive, and it is only as putrefaction or secondary decomposition set in that foul odours arise. This occurring in hundreds of instances makes the sewage very much more foul than it otherwise would be, and its emanations more malodorous.

Intercepting trap on house drains.—The intercepting trap was a "fad" on the part of a certain Medical Officer, who was consulted by the Local Government Board in the preparation of their Model Bye-Laws in 1876; whilst being correct in theory, it has many drawbacks in practice, and has tended to obstruct the ventilation of sewers through the house drains. This will be adverted to in a later paragraph.

The Model Bye-Law says that there shall be one trap to each house, with an inlet on the house side of the trap, and a tall shaft from the upper end of the drain.

This has been found to be so great an objection that in many towns they do not insist upon a trap at all, except where the drain runs beneath the house (amongst these towns may be mentioned Leicester, Barrow-in-Furness, Halifax, Stoke-on-Trent, Lewisham, Peterborough, and other places); whilst in the majority of towns in England where the Model Bye-Laws have been adopted, the Local Authority only insists upon one trap to each block of houses, this being the practice at Grimsby.

Owing to the small quantity and irregular flow of sewage from a small block of houses, putrescible matters are always left in the trap, sometimes for several hours, to be partly carried away by the next flush. Where more solid matters find their way into the drains these are washed along into the trap, there subside, and the trap becomes choked.

It has also been found in Grimsby that many drains from properties enter the sewers at so low a level that the junction is submerged, and when the sewage rises above its ordinary level, the air in the length of pipe between the intercepting trap and the sewer becomes compressed, and prevents a flow of sewage through the trap. I shall return to this in a later paragraph.

On account of this frequent blocking of the traps and the obstruction to the ventilation of sewers many municipal engineers desire to do without them, and, as I have already mentioned, some Local Authorities have ceased to use them. In view, however, of the probability of defects existing in the house drains, I do not recommend that the intercepting trap should be abandoned.

Surface ventilation.—When sewers were first generally constructed, from forty to fifty years ago, no ventilation was thought of, though, as there were no intercepting traps, the sewers were always ventilated through the tributary pipes. With the advent of the intercepting

* Report to Special Sub-committee of the Council, county borough of Grimsby.

trap the majority of these outlets were cut off, and manholes with ventilating covers were constructed on the recommendation of Sir Robert Rawlinson, the Chief Engineering Expert of the Local Government Board.

He suggested that manholes should be constructed at not more than 100 yards apart, and it is recounted that, on one occasion, having acted as advising engineer to a certain municipality, they sent to him a deputation complaining of the foul smells from manholes, and asking further advice. He replied tersely, "Put some more in."

I find from the replies to your queries, and from the reports of other municipal engineers, that the majority of towns have adopted surface ventilation, and that in the majority of them it has not been so successful as was hoped.

The Borough Engineer of Leicester, Mr. E. G. Mawbey, M. Inst. C.E., says:—"The system of surface grid ventilation has been well tried in Leicester under all conditions, including those most favourable to it, with the result that it has been found a fruitful source of nuisance by reason of the offensive emanations; and strenuous complaints from the public are very common, and of frequent occurrence. This has also been the case in the wide streets of new building estates, where the open grids have been placed throughout at short distances apart, with excellent sewers of the best type which have been regularly flushed. Pipe shafts have been erected at short distances from the grids complained of, and some of the grids left open, but these grids still acted frequently as offensive outlets, which has been proved by the many anemometer tests taken, as well as by the stench arising therefrom. Finally, these grids have had to be closed, which proved the fallacy of the idea, that, with a combination of open grids and tall shafts, the grids may be relied on to act as inlets only."

In Grimsby I find there are 446 manholes with ventilating covers, and that from time to time the majority of these have been complained about quite as strenuously as has been done at Leicester. In many cases orders have been given for the manhole covers to be plugged or stopped, so as to prevent the foul odours passing through.

The policy of closing the manhole covers without providing other means of egress for the foul air only results in greater offensiveness in the adjacent manholes, with the risk of forcing the foul air through the traps in the near neighbourhood, and producing a similar nuisance in a more confined situation.

Many attempts have been made to filter the air as it passes up the manhole, either through trays of charcoal or sheets of felt, and in other ways, but they have, without exception, been failures.

An effective method of deodorisation is by arranging chemicals so as to have a continual flow of chemicals into the sewer air (the most modern of these being the "Reevozone," where two chemicals flowing out of separate jars come in contact, and form an excellent disinfectant), but these methods are so expensive that no Local Authority is likely to maintain them for any lengthened period.

The theory of sewer ventilation.—The theory of ventilation in a room is a continuous inflow of fresh air, so arranged as not to produce a draught, and a constant outflow of foul and exhausted air. In the ventilation of a sewer the objection to a draught does not obtain, and all that is necessary is to induce a continual flow of air. It is alleged that this can be obtained by the following means (and this theory has been officially approved by the Local Government Board), viz., by fixing an inlet at or near the surface of the ground at the lower end of the sewer, and fixing a tall shaft at the other, or upper end of the sewer; the current of air will always be downward through the surface ventilator, and upwards in the tall shaft. This has not been borne out in practice, although it must be admitted that in the majority of cases the theory is correct; yet the number of cases when the current is down the tall shaft and up at the surface ventilator is so great as to prove that there is no rule. The direction of the flow of air is affected by the direction of the wind, the flow of sewage, the gradient of the sewer, reverse currents of air caused by surrounding buildings and other circumstances.

The direction of the flow of air in sewers.—It is generally supposed that the flow of air in a sewer is in the opposite direction to the flow of sewage, but this again is not found to be always the case, although it is true in a preponderating number of cases. The number of exceptions is so very large as to show the inadvisability of depending upon surface openings always acting as inlets, and tall shafts always acting as outlets, even when the tall shaft is fixed at the highest point of the sewer, and the inlet at the lower end of the sewer.

Vent v. *ventilation.*—The passage of large quantities of air through the sewers, whilst tending to keep the sewers sweet, is not an unmixed blessing, inasmuch as it means that large quantities of foul air are passing out from the sewer in one place or another; it also has the effect of evaporating large quantities of the foul liquids flowing along the sewers, as well as the moisture in those matters adhering to the sides of the sewers.

In my opinion, the ventilation of sewers is not desirable, except on those occasions where workmen have to descend for certain purposes. In this case, the opening of manhole covers in the neighbourhood for some period of time before the workmen descend will ventilate that portion of the sewer, and the men may descend with safety.

It will be recognised that according to the quantity of sewage flowing at different periods, there are different quantities of air in the sewer at different times; and that when the sewage is increasing in bulk, or rising in the sewer, the action of all the inlets is stopped, and under certain circumstances every opening to a sewer, whether at the surface or at a height above the ground, becomes an outlet. I am of opinion that a current of air along a sewer is not a necessity, and that what is required is a free vent for sewer air.

In summer also the air in the sewer is cooler, and consequently heavier, than the external atmosphere, and it will be seen how improbable it is that warmer air will flow down through the surface ventilator in order to push cold, heavy, foul air up a tall shaft.

The direction of the current in a ventilator (whether surface or shaft) is chiefly affected by the wind, either (*a*) by direct impingement into the opening, or (*b*) by indirect action in blowing across the opening. It has already been stated that the opening at the lower level is not always the inlet, and the opening at the upper level is not always the outlet, but that the direction of the current is governed by the direction of the wind. Therefore if all the vent openings are placed at the high level, the sewer gas will be discharged in such a position that it cannot harm anybody.

(*To be continued.*)

THE St. Bride's Press, Limited, 24, Bride-lane, London, E.C., is about to publish, from its works, 13, New Street-hill, Shoe-lane, Fleet-street, London, E.C., a book, entitled "How to Become a Municipal Engineer," by Mr. J. Freebairn Stow, Civil Engineer, Member of the Incorporated Association of Municipal and County Engineers, Member of the Society of Engineers, &c. The author is engineer and surveyor to the Uxbridge Rural District Council, and was previously in the employ of the Public Works Department, Cape Colony. He has endeavoured to place before those about to embark in the profession of civil engineer, or, more properly speaking, that branch of the profession which is known as "municipal engineering," the duties and responsibilities which an engineering pupil must undertake during his term of apprenticeship. The work is believed to be the first of its kind, and is written in as practical language as possible. It will be on sale at 1s. net.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

THE HOUSING PROBLEM IN RURAL DISTRICTS.

A GENERAL meeting of the members of the Incorporated Society of Medical Officers of Health was held on Friday evening at 197, High Holborn, W.C. Dr. J. C. McVail, president, occupied the chair, and among those present were Drs. J. T. C. Nash, E. S. Hoare, J. Scott Tew, E. Seaton, W. H. Symons, W. R. Hunter, P. Bangay, Shirley Murphy, A. Newsholme, A. Richards, H. C. Jones, G. Reid, C. E. Paget, E. F. Willoughby, J. H. Beale Collins, O. Field, J. McCathill, and F. J. Allan, hon. secretary. Hearty congratulations were tendered to Dr. McVail upon his recovery from a long and tedious illness.

Dr. C. E. PAGET, M.R.C.S., D.P.H., Medical Officer of Health for the County of Northampton, read an interesting paper upon "Some of the Principles Involved in Schemes for the Better Housing of Rural Populations." He pointed out that the housing question presented features of complexity and difficulty hardly equalled by other social problems. It was a question which could not be considered as affecting towns and urban centres, but also purely agricultural districts. The underlying fact was to be found in the ebb and flow of commercial prosperity. For instance, those working in large towns were familiar with the substitution of large business premises for dwelling houses, the poor being gradually squeezed into more restricted areas; there was the flow of rural population into urban districts increasing the inevitable competition for rooms and sending rents up still higher. Various schemes for dealing with the problem had engaged the attention of Municipal Authorities for years. They, as well as philanthropists, had worked in the direction of erecting model dwellings on the flat system; on the whole this had been found to be a satisfactory system, even if it were only partial in its ameliorative operation. Many pinned their faith to cheap locomotion to outlying suburbs as a means for relieving urban congestion. But the tendency of the day appeared to lie in the direction of encouraging the Local Authorities to provide healthy houses for the wage-earning classes. Now the housing question was a rural as well as an urban question; in some agricultural districts the need for better housing accommodation was very great. With the flow of rural populations into the towns it might be thought there was an abundance of cottage accommodation. But, naturally, with empty cottages the rents decreased; their value fell off, and consequently owners declined to keep them in repair. New cottages were not erected, for this was, under present circumstances, a totally unremunerative form of investment. Existing cottages were in many cases totally unfit for occupation; yet to close them would be to aggravate the evil. Dr. Paget referred to the reports of Commissions and investigations into the subject, and explained the four kinds of ownership of rural property, viz., (1) estate owners who provide cottages for some who work on their estates; (2) private owners who let cottages at the best rent they can obtain; (3) leaseholders and life-holders; (4) occupying owners — the last being rare. Dr. Paget then explained the reasons which prevented either class of owners attempting to improve the cottage accommodation in rural districts, and outlined a description of a village in Northamptonshire to serve as an illustration of the condition of cottages in small villages in rural districts. He explained the circumstances which had led up to the present position. Out of 146 cottages sixteen were unfit for habitation, twenty-one were in an unsatisfactory state, and many of the remainder were overcrowded; the population of this village of Spratton was 750. The Brixworth Rural District Council at length decided to approach the County Council under Part 3 of the Housing of the Working Classes Act, 1890. The necessary inquiry was held, but although the certificate was finally issued, the whole scheme ultimately fell through. One means of remedy, he thought, would be to provide for the Local Authority being compelled to go on with their scheme when it had been sanctioned by the County Council. A great difficulty in improving cottage accommodation in rural places was that the cost would have to be borne by the whole district rather than by the parish in which the improvement took place. This led to opposition. The principle underlying the problem was whether or not the expenditure of public money for the purpose of housing the poor in rural districts is justifiable. Within certain limits he thought such expenditure was right; but of two things he felt certain—any such expenditure should not be recklessly indulged in, and when shown to be proper it should be not less easy of accomplishment in rural districts than in urban districts. The Act of 1890 did not seem to be antagonistic to the principle of Rural Authorities becoming landlords, though opponents of this principle had certain strong grounds for their attitude. He analysed the Acts of 1890 and 1900, and pointed out that after all the trouble, time, and expense involved by an inquiry by a County Council, the Rural District Authority was under no obligation to adopt Part 3 of the Act. The case was quite different with an Urban District Authority, and in this respect the law badly needed amendment; to some extent the drawback was overcome by the Act of 1900. The substantial advantage of the recent Act was that it did away with the necessity, under certain circumstances, of waiting for an election of a new Board. Time alone would show whether the supposed simplification of procedure introduced by the 1900 Act would lead to any greater activity on the part of the Local Authorities. There was one provision in that Act which was possessed of possibilities in that direction, viz., if a Local Authority make default in regard to housing and the adoption of Part 3 of the Act, they would be liable to have their powers transferred to the County Council. The section provided that if the Parish Council resolve that the District Council should have exercised its powers under Part 3 of the Act, and if the County Council be satisfied after due inquiry that the District Council has so failed, they can then resolve that the powers be transferred. Leaving out the question whether a Parish Council was more likely to take a lead in the matter than the District Council—so far the Parish Councils had not been circularised by the Local Government Board as had been the District Councils—he was quite sure the Parish Council would only proceed in rare instances if the expense of providing cottages was likely to fall on the parish instead of the district in which that parish is situated. This raised a great question of principle—Should the expense of building cottages fall on the parish in which they were built or upon the district in which the parish is situated? Various views on this had been expressed, and several interpretations as to the meaning of the Legislature had been forthcoming, but undoubtedly in deciding the point the circumstances of each case ought to be taken into account. In very special areas it might be fair to even still further restrict the area of contribution. On the whole, the argument was rather in favour of the district than the parish bearing the burden caused by the erection of cottage property. But the Act of 1900 seemed to imply that no other area except that for which the cottages are required should bear the cost, though the machinery that Act provided appeared to be more easily workable than the other. There was, however, still room for an enlargement of the existing powers of County Councils in regard to this question, and for the work to be systematised and rendered less limited by

local criticism. He trusted to receive some expression from the members of that Society in favour of the better carrying out of the Housing of the Working Classes Acts in rural districts, particularly in the direction of a simplification of procedure, which would encourage greater activity on the part of Rural District Councils. (Cheers.)

Drs. G. Reid, J. Scott Tew, A. Newsholme, H. Beale Collins, S. Hoare, E. Seaton, Shirley Murphy, and the President took part in the debate which followed, general agreement being expressed with the views of Dr. Paget, to whom a cordial vote of thanks was accorded for his address.

BRITISH CONGRESS ON TUBERCULOSIS
FOR THE PREVENTION OF CONSUMPTION.

As already announced, His Royal Highness the Prince of Wales has graciously consented to open in person a British Congress on Tuberculosis in the Queen's Hall, London, at three o'clock in the afternoon of Monday, the 22nd July, 1901; and it has been decided that the Congress shall be held from Monday, 22nd July, to Friday, 26th July.

Every British Colony and Dependency is invited to participate by sending delegates; while the Governments of countries in Europe, Asia, and America are invited to send representative men of science, and others, who will be the distinguished guests of the Congress.

The information already gained, both at home and abroad, shows that consumption and other forms of tuberculosis, although preventable and controllable by intelligent precautions, still remains the direct cause of a high rate of death and sickness. In the United Kingdom alone some 60,000 deaths are recorded annually from tuberculosis, and it is stated on good authority that at least thrice this number are constantly suffering from one form or another of the disease.

The knowledge of these facts, and the recognition that the disease is peculiarly amenable to open-air treatment, has aroused profound international interest in the question; and in many countries public authorities have been led to put in force preventive measures directed against the propagation of consumption between human beings, between animals, and between human beings and animals.

The object of the forthcoming Congress is to exchange the information and experience gained throughout the world as to methods available for stamping out this disease. Papers will be read, and clinical and pathological demonstrations will be given; while the museum, which is to be a special feature of the Congress, will contain pathological and bacteriological collections, charts, models, and other exhibits.

Authorities in this and other countries will be invited to supply documents bearing upon the historical, geographical, and statistical aspects of the subject; while as a result of the papers and discussions, practical resolutions will be formulated which will serve to indicate the public and private measures best adapted for the suppression of tuberculosis.

The work will be divided into four sections as follows:—

Section I.: State and Municipal.—President, Right Hon. Sir Herbert Maxwell, Bart., M.P., 49, Lennox-gardens, S.W. Secretaries, Dr. Bulstrode, L.G.B., Whitehall, S.W.; Dr. James Niven, Town Hall, Manchester.

Section II.: Medical, including Climatology and Sanatoria.—President, Sir R. Douglas Powell, Bart., M.D., 62, Wimpole-street, W. Secretaries, Sir Hugh Beevor, Bart, M.D., 17, Wimpole-street, W.; Dr. Hector Mackenzie, 59, Welbeck-street, W.; Dr. R. W. Philip, 45, Charlotte-street, Edinburgh.; Dr. William Calwell, 1, College-square North, Belfast.

Section III.: Pathological, including Bacteriology.—President, Professor Sims Woodhead, M.D., 6, Scrope-terrace, Cambridge. Secretaries, Dr. Wethered, 83, Harley-street, W.; Professor Rupert Boyce, Liverpool (University College); Dr. E. J. McWeeney, 84, St. Stephen's Green, Dublin; . Dr. Perkins, 41, Wimpole-street, London, W.

Section IV.: Veterinary (Tuberculosis in Animals).—President, Sir George Brown, C.B., Bryn Hyfryd, Harrow. Secretaries, Professor Hobday, F.R.C.V.S., 27, Lower Phillimore-place, Kensington, W.; Professor Bradley, M.R.C.V.S., Royal (Dick's) Veterinary College, Edinburgh; Professor H. Woodruff, M.R.C.V.S., Royal Veterinary College, Camden Town, N.W.

Exhibition: The Museum of Pathology, Bacteriology, and Public Health.—Chairman of Museum Committee, Professor Sims Woodhead, M.D., F.R.S.E., 6, Scrope-terrace, Cambridge. Secretary, W. Jobson Horne, M.B., M.R.C.P., 27, New Cavendish-street, Harley-street, W., to whom all correspondence relative to the Museum should be addressed.

The following are the rules and regulations:—(1) The Congress shall consist of honorary members, delegates, and members.

Honorary members shall be persons nominated by any foreign Government or University, or by the Executive Committee, and shall not pay any subscription whatsoever.

Delegated and ordinary members shall be other persons, British, colonial, or foreign, who may wish to attend, including representatives from Governments or institutions within the British Empire.

(2) Delegated and ordinary members will receive their cards on forwarding the sum of £1 to the Secretary-General of the Congress, 20, Hanover-square, W.

(3) The holder of a ticket of membership is entitled to admission to all the meetings of the Congress, and to receive the "Transactions" and other publications.

Tickets to social gatherings and excursions will be allotted in order of application, or by ballot if necessary.

(4) As the expenses of the Congress will be very considerable, donations to the Reception Fund are earnestly invited. Donations of more than one guinea will be considered as including member's subscription, and will entitle the donor to all privileges of membership. Donations from corporate bodies may include the subscriptions of representatives.

(5) The official language of the Congress shall be English, French and German, and authors of papers are requested to supply beforehand abstracts for translation.

(6) Each Sectional Committee shall draw up its own working programme as to papers to be read, discussions on the subjects proposed, and miscellaneous communications. The various Sections will meet on Tuesday, Wednesday, Thursday, and Friday, from 9.30 to 1.30.

(7) The speeches delivered at the general assemblies, and the papers read before the Sections, will be published in the record of the proceedings of the Congress; but as regards miscellaneous communications and discussions, the discretion in respect of publication will lie entirely in the hands of the "Transactions" Committee and the Presidents of Sections. Each speaker opening a discussion will be limited to thirty minutes' duration, and each subsequent speaker to ten minutes.

(8) An abstract of every paper and communication must be sent to the Secretary-General, 20, Hanover-square, at the latest on or before June 15th, 1901.

Arbitration proceedings were concluded at the Midland Hotel, Bradford, last week, with reference to the price to be paid to Mrs. Crofton, of Burley Hall, by the Burley-in-Wharfedale Urban District Council for land on Burley Moor required for waterworks purposes. On behalf of the claimant, the value of the property was placed at £10,600, and for the Council at between £900 and £1000.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

Those engineers and chemists who are interested in the bacterial treatment of sewage will find Drs. Clowes and Houston's third and recently-issued report to the London County Council on "The Bacterial Treatment of Crude Sewage at the coke-beds at Barking and Crossness" (price 2s. 3d.) of considerable importance. Incidentally, I may mention that the engravings taken from photographs of these infinitely minute organisms, commonly known as bacteria, and admirably reproduced in the report, enlarged about one thousand times, might be usefully shown to inquisitive Councillors—a class of whom refuse to believe in the existence of any other matter in the universe, except themselves, unless the can actually see it, and who are represented on almost every deputation visiting sewage works. The coloured diagrams showing the number of spores of bacilli and bacteria in the sewage, and in bacteria bed effluents, and the very fully-detailed report of the bacteriological experiments, make the report the most important of its kind from a bacteriological point of view yet published.

From an engineering point of view the report does not assist in carrying us much further than where we were. It may, however, be useful to notice that coarse beds of Kentish ragstone of a mesh between ½in. and 4in. gave better results as regards purification than beds of coke, and that their capacity was better maintained, but that fine beds composed of coke breeze of a mesh between $\frac{1}{16}$in. and ½in. produced a better effluent, and are better able to remove organic matter in solution, than beds of ragstone of similar gauge. The capacity of fine beds after a few months' work is also, it is to be noticed, found to be about 100 per cent. greater than coarse beds.

It is observable that all the experiments were conducted with a two hours' contact. Why the original method, adopted we believe, by Mr. Dibdin four years ago should be so closely followed we are not informed. It would surely be of some educational value if the chemists were to experiment with the treatment of sewage under different periods of contact, or, on the other hand, to definitely explain that this is the absolutely perfect period, and that no other contact period can or ought to be adopted. The experiments do not, we think, evidence that originality of treatment which we might perhaps reasonably expect. Possibly the co-operation of an engineer in conducting the experiments would have been of material assistance, for such does not appear to have been the case.

The method of screening the crude sewage has been still adhered to. Rapid sedimentation before discharging the sewage upon the bed, but without septic action, is advocated; and here again no experiments appear to have been conducted to test the applicability of closed or open septic tanks. True, it is suggested that intermittent septic treatment is not deemed likely to be suitable; but is not this begging the question, for I imagine no experienced engineer advocates such a mode of treatment? Septic or sedimentation tank treatment, as is well known, is continuous and not intermittent. Then, again, there does not appear to have been, nor is it suggested as to the future that experiments will be conducted to test any one of the continuous methods of bacterial treatment.

The experiments are useful in showing that a primary or coarse-grain bed, 13ft. in depth, gives as good results as a shallow bed 4ft. in depth, and that even the bottom of the 13ft. bed was well supplied with oxygen. This may help to remove the current opinion, and one which prevails at the Local Government Board, that a depth of 4ft. is the best possible for bacteria beds.

The tables relating to the temperature readings of the atmosphere, and of the crude sewage and effluents from the beds, are explanatory of the non-influence of frost on the beds, the temperature of fresh sewage and of the interior of the beds being always higher than that of the external air. The tables showing the percentage of oxygen and of carbon dioxide in the beds—the average being 5·7 CO_2 and 8·0 oxygen as compared with the average percentage of carbon dioxide in air being 0·04, and of oxygen 20·96—are also interesting. Notwithstanding these I am bound to confess that from an engineering point of view the experiments are not, as I have already observed, so helpful, varied, or original as one had reason to expect. The London County Council are the richest Local Authority in the kingdom, and can afford to conduct experiments on a more perfect and liberal scale than any other Authority, and something more should be attempted than a repetition of experiments commenced long ago by very small Authorities.

I suppose that all surveyors throughout the kingdom will by this have renewed their acquaintance with the difficult problem of quick removal of snow from the public thoroughfares. It is, I am told, a task which somehow yields no satisfaction, for the British public in most of our towns are so indiscriminating as to expect every yard of public footways to be cleared within twenty minutes after a snowfall. Municipal surveyors are not, however, wizards to command that with every snowflake a workman shall come down with it to clear it off; but this, it is said, is just what some less enlightened ratepayers imagine. The task, however, is a Gargantuan and a costly one; but if the British public are willing to pay for it, surveyors will, I know, be equal to the occasion.

For the successful carrying out of the work, the organisation should be thorough and effective, otherwise the work is inefficiently done, and labour is wasted through the scheme having been imperfectly prepared. The best systems which I have been fortunate enough to observe are those which have been prepared months before a snowfall threatened. Then, when the snow at last came, all the men and machinery fell into work without chaos or waste of time or labour, as though they had been rehearsed for it, and miles of footways were entirely cleared of snow, and roadways opened with snow-ploughs before citizens began to move about.

In these cases I found that the surveyors allotted out their districts into a considerable number of smaller ones, to each of which a responsible ganger with a given number of men was sent. Each of these gangers is supplied with a printed sheet containing the names of the streets which he has to clear with his men, and if any additional men are subsequently engaged at the depôt they are ordered to take their place in the gang number shown on the printed sheet which is also given them. They have thus no difficulty in finding or taking their place in any gang, and the leader books each man's time on coming on. In a similar way other workmen get out with the snow plough, while carmen are set to cart away the snow on a pre-arranged and printed programme, and supervised by the surveyors themselves, who moved through the districts, observing the progress made, strengthening some gangs which were inadequate, by the addition of men from others which were too large, the work went along smoothly and expeditiously, and with infinite credit to the surveyors concerned, and laudatory comments from the public Press.

Writing of snow ploughs reminds me that the several firms of Henry Wadsworth and Sons, Halifax; Wm. Glover and Sons, Warwick; and the Bristol

Wagon and Carriage Company have all brought out special forms of snow ploughs, and I understand that these are generally kept in stock by them. It appears to me that a snow plough specially adapted for clearing footways is much required. In Russia such a snow plough, drawn, I believe, by two men, is greatly used, which can clear over a mile an hour. A third man follows with a hand-broom, sweeping away any small portions which have been missed by the plough, and the work, it is said, is effectually done. Rough hand ploughs for removing the snow from the channels in town roadways are sometimes, as I have seen, used, but these will bear considerable improvement.

SENEX.

National Health Society.

OFFICIAL TRANSACTIONS.

A VERY satisfactory result of the recent examination on "First Aid," held in Oxford, has just been received. The report of the examiner states that the "standard of efficiency in most cases was high, and the candidates generally showed an intelligent grasp of the subject." Twenty-nine candidates presented themselves from various centres, and only two failed to satisfy the examiner. The lectures in this county have been given by Miss Christine Hall.

THE attention of readers is again called to the fact that training lectures for Sanitary Inspectors will be commenced on January 29th. Lectures on "Nursing" and "First Aid," in connection with the training course for the diploma of the National Health Society, will be commenced on Thursday, January 24th, and Monday, January 28th, respectively. Intending students should communicate without delay with the Secretary, 53, Berners-street.

ASSOCIATION OF NATIONAL HEALTH WORKERS.

MEMBERS are reminded that their annual subscription to the Association of 2s. 6d. became due on January 1st, and should be sent to Miss Christine Hall, 78, Oxford-terrace, W.

On Saturday, January 5th, an excursion was made by members of the Association of National Health Workers to the North London Consumption Hospital, Mount Vernon, Hampstead. Dr. Squire kindly received the visitors, and escorted them over the new wards and balconies recently prepared for the "open-air" treatment of consumption, or rather the hygienic treatment of consumption, of which open air is only an important feature. It was difficult to believe that patients could enjoy and benefit by sleeping in the open air under the inclement conditions that have lately prevailed—the minimum temperature of the night of the visit was below freezing point. However, conversation with the invalids elicited the fact that they never felt cold, never caught cold, and never wished to sleep indoors again. A considerable amount of exercise forms part of the cure with absolute rest for several half-hours during the day, and though not "stuffed" with food—an unpleasant feature of some up-to-date methods of treatment of consumption—the patients are given a very generous diet. Some idea of the thorough ventilation of the hospital may be gathered from the statement of the Matron that some twenty broken door handles had to be replaced that very day, and several window panes re-glazed. When the members had well explored wards and balconies, day-rooms and dining-rooms, out-patients'-rooms, and recreation-rooms, they were hospitably entertained to tea by the Matron.

ROYAL COMMISSION ON SEWAGE DISPOSAL.

THE following circular letter has been addressed to Local Authorities:—

Royal Commission on Sewage Disposal,
39, Victoria-street, S.W.,
December, 1900.

Sir,—I am directed by the Royal Commission on Sewage Disposal to inquire whether the District Council have conducted any experiments as to the purification of sewage by any of the following or similar methods:—

A. Closed septic tank and contact beds.
B. Open septic tank and contact beds.
C.* Subsidence tanks and contact beds after chemical precipitation.
D. Subsidence tanks and contact beds.
E. Contact beds.
F. Closed septic tank followed by continuous filtration.
G. Open septic tank followed by continuous filtration.
H. Chemical precipitation, subsidence tanks, and continuous filtration.
K. Subsidence tanks followed by continuous filtration.
M. Continuous filtration.

If so, I am to state that the Commission would be much obliged if the District Council would kindly furnish them with the results of such experiments.

Forms have been prepared in regard to each of the above-mentioned methods, lettered A, B, C, D, &c., showing what results the Commission are anxious to see, and it will be of considerable convenience to the Commission to have the results submitted on these forms.

On learning what experiments have been conducted I shall be happy to furnish you with suitable forms.

I am, Sir,
Your obedient servant,
F. J. WILLIS,
Secretary.

The Clerk of the District Council.

SCARLET FEVER IN YOUNG CHILDREN.

SCARLET fever has become of late years a much milder complaint. How much of this is due to the greatly increased use of isolation hospitals, and how much to an amelioration in the natural type of disease, may be matter of dispute; but it still remains true that its chief fatality is at the ages under five, when one out of twenty-eight attacked die; while at ages from five to ten only one out of 333 attacked die, and at subsequent ages there are practically no deaths. All these facts point to the importance of protecting children under five from exposure to infection. Chief among such means of infection is the attendance of children in the infants' class at school long before the age at which compulsory school attendance begins. If any great educational advantage were associated with the attendance at school of children from three to five years of age, a case might possibly be made out for the continuance of what now means a heavy annual death roll.

I am prepared to admit that the advantages of elementary education are so great as to render the sacrifice of life or of health for a minority a public necessity. The only point is to ensure by proper precautions that

* The expression "subsidence tanks" is intended to denote tanks which are used so that little or no "septic" action is produced.

this sacrifice should be the least possible. But in the case of infants under five years of age it does not appear to me that there is any educational advantage at all commensurate with the present loss of life caused by such attendance in infant schools.—*Dr. A. Newsholme, Annual Report*, 1899.

Sanitary Inspectors' Associations.

THE NATIONAL UNION.

The fourth meeting of the session of the North-Western District Centre of the National Union of Sanitary Inspectors was recently held at the Co-operative Hall, Manchester, Mr. Robert Lowe, of St. Helens, presiding. Representatives were present from a large number of towns. An interesting paper was read by Mr. G. W. Laskey, Chief Sanitary Inspector of Eccles, who dealt in the main with the question of sanitary arrangements in private houses, and enforced the necessity of fitting up the most modern system. As to the question of the responsibility for providing funds for bearing the cost of changing the systems, he could see nothing logical in the property owners' objection of bearing the expense. The change to an improved and more healthy system certainly increased the value of their property, and brought them in a better return. If once the principle of improving property out of the rates were admitted, there would be no end to the claims on the public purse, and owners of property which was satisfactory in respect of all its sanitary arrangements would naturally object to having to contribute anything towards the cost of improving that of others. He contended that they should try to arrive at something like uniformity of action. The time had arrived when no more antiquated structures should be allowed to be erected, especially in those districts which were furnished with adequate water supplies and efficient sewage systems. A great deal of success might be attained by persistently calling attention to the defects in those old structures, and by dwelling upon the responsibility of owners for any cases of infectious diseases which might be attributable to those conveniences. In a few years hence owners of property furnished with the old systems would be compelled to adopt more modern requirements.

LAW CASES.

Tuberculosis in Cows.

An important case to farmers and milk consumers was tried by his Honour Judge Whithorne and a jury at Birmingham County-court. An action was brought by Clement Haynes, Lea-end, near Alvechurch, farmer, against George Keys, of the Home Farm, King's Heath, farmer, to recover £33 damages for breach of warranty. In September last the plaintiff agreed to purchase three cows from the defendant for £33. The defendant, he said, warranted the cows to be perfectly right and healthy. He left the cows for three or four days at the defendant's place till he could send for them. On the fifth day he received a letter from the defendant saying that one of the cows was ill, and soon after another letter that it had died from eating acorns. A post-mortem examination showed that the lungs of the dead animal were "rotten with tuberculosis." Of the other two cows one was healthy and the other was affected with tubercle. On the advice of his solicitor, the plaintiff removed the two cows and paid the £33 to the defendant without prejudice. The action was brought to recover the money from the defendant. It was explained that the afflicted cow removed by the plaintiff would not be used by the plaintiff as a milch cow, but would be killed after calving. The defence was a denial of the warranty. One of the veterinary witnesses (Mr. Gould, of Redditch) said that 40 per cent. of the dairy cows in the county suffered from tuberculosis. He explained that by this he meant housed cows.

His Honour: That is a matter of fearful public interest. Witness said it did not affect the milk unless the tuberculosis extended to the udder, then it was most dangerous.

The jury gave a verdict for the plaintiff for £22 10s.

Defiance of the Factory Act.

Mr. Rose, at the West London Police-court, heard the adjourned summonses against the Henrici Laundry Machinery Company, Limited, for employing two women between one and two o'clock on December 17th, being the time specified for meals; and also for employing a woman between 7 a.m. and 7 p.m., the specified period for work being 8 a.m. to 7 p.m.

Her Majesty's Factory Inspector stated with regard to the first two cases that the offence was a technical one merely, and if the laundry had been well managed in other particulars no action would have been brought, but in this case the laundry had defied the law, and had failed to comply with any previous instructions. He therefore asked for a full penalty.

The Magistrate imposed a penalty of £2, with 14s. costs in each case.

It was proved in the third case that no notice of variation of the period of employment had been posted.

The Magistrate imposed the full penalty of £3, with 4s. costs.

FORTHCOMING MEETINGS.

January.

Friday, 18th.—Institution of Mechanical Engineers.—Annual general meeting: Further discussion on "Power, Gas, and large Gas Engines for Central Stations," by Mr. Herbert A. Humphrey. 8 p.m.

Friday, 18th.—Epidemiological Society.—Messrs. Louis Parkes, M.D., and Samuel Rideal, D.Sc., F.I.C., on "A Suggested Method of Preventing Water-borne Enteric Fever among Armies in the Field." 8.30 p.m.

Monday, 21st.—Surveyors' Institution.—Junior meeting. Mr. L. S. Wood on "Income Tax, Schedule A." 7 p.m.

Tuesday, 22nd.—London County Council resumes.

Thursday, 24th.—Society of Architects.—Sessional meeting. 8 p.m.

Thursday, 31st.—Association of Birmingham Students of the Institution of Civil Engineers.—Annual dinner at the Grand Hotel, Birmingham. 7.30 p.m.

February.

Saturday, 2nd.—Sanitary Inspectors' Association.—Dinner at Holborn Restaurant.

Mr. James Mansergh, C.E., presented a voluminous report to the Richmond (Surrey) Town Council last week, advising it to abandon any further extension of the borough waterworks, and seek a supply from the Southwark and Vauxhall Water Company, which already gives part of the supply. The town carried on its own waterworks for a quarter of a century, and spent nearly £100,000 in digging for water in the chalk and other underlying beds, there being a strong feeling in the borough against the Southwark and Vauxhall Company, but Mr. Mansergh said they had experimented long enough. No action was taken in the matter.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

JANUARY 17, 1901.

THE BEER POISONING QUESTION.

THE Government have appointed a Royal Commission to inquire into the epidemic of poisoning through the presence of arsenic in beer. This step is a natural one, and well fitted to allay the public anxiety that has been excited by recent revelations in Manchester and the Midlands. But the inquiry is not to be limited to beer alone. The instructions of the Commissioners are "to ascertain the amount of the recent exceptional sickness and death attributable to poisoning by arsenic; whether such exceptional sickness and death have been due to arsenic in beer, or in other articles of food or drink; and if so, to what extent, by what ingredients, or in what manner arsenic was conveyed, and in what way any such ingredients became arsenicated; and if it is found that exceptional sickness and death have been due to arsenic in beer, or in other articles of food or drink, by what safeguards the introduction of arsenic therein can be prevented." The Commission is a strong one. It comprises Lord Kelvin; Sir W. Hart-Dyke; Sir W. S. Church, president of the Royal College of Physicians; Professor J. E. Thorpe, Government Analyst; Mr. H. Cosmo Bonsor; and Dr. A. Whitelegge, Chief Inspector of Factories; with Dr. G. S. Buchanan, of the Local Government Board, as secretary. So far as the facts are concerned, the way has already been paved by the report of the Manchester Commission, which is now a matter of public knowledge. Though the scope of the inquiry is in its terms a broad one, there is no doubt that the principal subject of investigation will be beer, with special reference to the use of substitutes in brewing through which arsenic may be introduced, and in so far it will open up afresh the whole question dealt with by the Pure Beer Commission several years ago. Recent experience has made the country feel that the report of that Commission was not justified. There is a strong opinion prevalent that legislation to secure the purity of beer is required, both in the interests of the public health and in the interests of the greatest of our national industries. And that feeling is already finding voice, in no uncertain manner, with men highly qualified to indicate the probable course of future legislation. Mr. Chaplin has on more than one occasion of late stated most emphatically that legislative action is necessary, and though no longer a member of the Government, his influence is certain to carry great weight with the Ministry. And Lord Londonderry, who is a member of the present Government, at the annual dinner of the Newcastle Farmers' Club, the other day, said that legislation to ensure beer sold to the public being made with honest, sound materials—that is, as may be gathered from an immediately preceding sentence, pure malt and hops—was an absolute necessity. To these statements must be added that of Mr. Walter Long, the President of the Local Government Board, whose pronouncement is eminently satisfactory from a public health point of view. Mr. Long mainly dwelt upon the financial aspect of the question, but observed, *en passant*, that if it was a question of public health, taxation would have to stand on one side altogether. All such utterances must, of course, pending the report of the Commission, be taken with a certain degree of reserve, but they are, in a sense, authoritative, as indicating the present temper of the Government and the nation. Meanwhile it is interesting to note that a step in the direction foreshadowed in a recent leading article appearing in these columns has been taken, an influential association having been formed to promote the purity of beer by parliamentary measures and otherwise. Mr. Chaplin has made an appeal through the Press for the co-operation and support of all who are interested in the subject, and we feel quite sure there are many among our readers

who will gladly give any assistance in their power to a movement which is so directly associated with the health of the people, and consequently has every claim upon our sympathies.

The Diet of the Poor.

Some Edinburgh doctors have recently concluded an exhaustive investigation into the nature of the diet of the poorer classes of that city, and one of their number, Dr. Noel Paton, gave the results at which they had arrived in a public lecture last week before the Scottish Society of Economists. The object of their researches was to ascertain exactly what dietary was necessary to constitute the proper food supply of the average working man, and the conclusion reached was that the poorer classes of working people did not receive the food necessary for what had been estimated, as the amount of energy an ordinary labourer should be able to expend on his work. As a matter of fact, he said, taking some examples of the daily diet of those of the poorer classes whose wages were irregular, it had been found that the free labourer in these cases received less energy-producing food than did the inmates of our asylums, hospitals, and prisons. He instanced as rather a curious thing in this connection that oatmeal—which was at one time supposed to be the staple food of the poorer classes in Scotland, and which contains the elements of an almost ideal food—came far down the list of the various articles of dietary in the proportion used. Bread, potatoes, milk, vegetables and beef, all preceded it, the average use of oatmeal in the cases investigated being only 1½ oz. per day. He suggested that some good might be done, as a first step, by distributing simple tables showing the amount of work-producing power which could be got for a pennyworth of ordinary articles of diet. The regrettable thing about this state of matters is that it is not a question of want of money. The change—for a change it undoubtedly is, and a change for the worse—may partly be attributed, we believe, to the rise in the standard of social comfort which has accompanied the rise in wages for working men, resulting in the discarding of many of the old-fashioned simpler articles of diet for others that are more expensive, but have less life-sustaining power in them.

Sewage Purification in Dumfries.

It has been amusing to watch the wriggling of the Town Council of Dumfries in their attempts to deal with the question of the purification of their sewage. We have already in these columns referred to the previous history of the matter; how, in consequence of the pollution of the river Nith—into which the sewage of the town has hitherto been discharged—the Corporation have been ordered by the Secretary for Scotland to provide a satisfactory system of sewage purification within a limited time, and how after consulting Mr. Carter, C.E., Edinburgh, he recommended the adoption of a scheme which he estimated would cost £30,000. The Council, however, were staggered at the idea of the cost, and resolved to send a deputation of inquiry to investigate the matter for themselves. The deputation visited various sewage works in England and Scotland, and returned to express the opinion that the bacterial process, as they had seen it in operation, particularly at Sutton and Barrhead, was most suitable for Dumfries, where the sewage was mostly domestic. But this was precisely what Mr. Carter had already recommended. Still unsatisfied, the members of the Council suggested all sorts of devices to enable them to wriggle out of the difficulty. The Provost stuck to his opinion that at no place which he had visited had he seen finer sewage disposal works than the Nith itself, with all deference to Colonel Gore Booth, who conducted the inquiry into the pollution of the river, and whose views on sanitary science he characterised as very much in advance of this generation, probably of several generations to come—we should be disposed to add, most certainly in advance of the worthy Provost himself. The upshot of the whole matter was the adoption of the Committee's recommendation that Mr. Carter should be asked to meet the Council in conference to explain various details. No doubt, notwithstanding all these kickings against the pricks, Mr. Carter's scheme will have to be adopted.

A Good Record in the West Riding.

The last meeting (prior to the election) of the West Riding County Council was held last week, and the Chairman took advantage of the occasion to review the work of the past three years. Two or three points are worthy of notice. In at least two important items he was able to report a decreasing expenditure. In 1899 and 1900 the cost of lunacy in the county district averaged £51,985, against £53,375 in the three preceding years. This is decidedly an encouraging fact, more particularly when most counties are compelled to report the reverse. It was also pointed out that the ratio of lunacy in the West Riding was 20·82 per ten thousand, as compared with 30·47 for England and Wales. Reduced expenditure was also reported in the main road accounts. In March, 1900, the total mileage of main roads was 1111 miles. Without in any way decreasing the efficient upkeep of these, the cost had been reduced from £146 to £133 per mile. The total expenditure for each of the last three years was:—In 1898, £165,224; 1899, £162,570; and in 1900, £151,477. Going on to refer to the other administrative work of the Council, the chairman said they were endeavouring to secure larger powers for district authorities in regard to tuberculosis, and 5101 samples had been taken in three years under the Foods and Drugs Act, and 196 convictions had been obtained out of 218 prosecutions. It was satisfactory to the Diseases of Animals Committee to be able to report that during the three last years there had been only one case of rabies in the Riding. Swine fever unfortunately showed a strong vitality, the outbreaks in the geographical West Riding being 188 in 1898, 225 in 1899, and

230 in 1890. The total county rate basis in 1898 was £7,157,022, and in December, 1900, £7,493,845. The number of county electors in 1889 was 242,060, and this year it was 280,142.

A Temporary Loss.

The retirement of Mr. E. T. Cook from the editorship of the *Daily News* is a distinct loss to the cause of social reform, but we trust it may only be of short duration. During the five years he has directed the affairs of our contemporary, every movement for improving the surroundings of the people has received a most cordial and sympathetic support. We can never forget that it was through the advocacy of the cause of the half-timer in the *News* that the country was aroused to the importance of the question, and Parliament was compelled to pass Mr. Robson's Bill, in spite of the opposition of interested manufacturers and even the Lancashire workers themselves. To Mr. Cook also we owe the sending of a special commissioner all over the metropolis to investigate the extent of the "house famine," which was the burden of complaint by many advocates of housing reform. Nor was he content when the vastness of the evil in London had been laid bare. Inquiries in rural parts, and particularly in the eastern counties, revealed a condition of things equally appalling, and it is to this work that the housing question occupied the foremost place in the list of urgently-needed social reforms. The predominating idea in all Mr. Cook's work was to get at the truth. Party cries, as such, had no influence over him, and the unquestioned honesty of all his actions won for him a position in journalism such as it is given few men to attain. There is, alas, such an air of artificiality in the daily Press of to-day, that the loss of such a worker is greatly to be deplored, and we trust it will not be long before Mr. Cook finds another sphere in which he may again serve the cause of reform.

Stamping out Disease.

A paragraph in the report presented by the West Hartlepool Town Council last week by the Medical Officer of Health shows how prompt action on the part of officials may be effectual in stopping the spread of disease. After enumerating the cases of zymotic disease during December, Dr. Morison said that the "two cases of small-pox were at once removed to the Port Sanitary Hospital. One case was the mother of a previous patient, the second was a sailor who came from Stockton, his ship having come from Bilbao. The Medical Officer of Stockton and the owner of the ship were both informed of the case. We can now congratulate ourselves that we are free from the grave danger of an epidemic. That the danger was great is shown by the strange fact that our cases were traced to no less than five separate and distinct sources of infection. In one case, owing to peculiar circumstances, I persuaded the man in the house to stay off work for a fortnight, and after speaking to your chairman promised him the amount of his wages for that time. In another case it was thought advisable to have all the wall papers in the house stripped off and the walls lime-washed. This was willingly done by the people, and as they are poor, I would ask that you bear the cost." This action of the Medical Officer is described by the local paper as "daring," as if it was very novel. We are afraid that too many do not realise that they have the power to take such measures, or some silly sentimental objection is allowed to prevent it being done. But why should it? The man loses his week or two week's work for the safety of the community, and it is far cheaper to pay him for it than to be overrun with small-pox or some other disease.

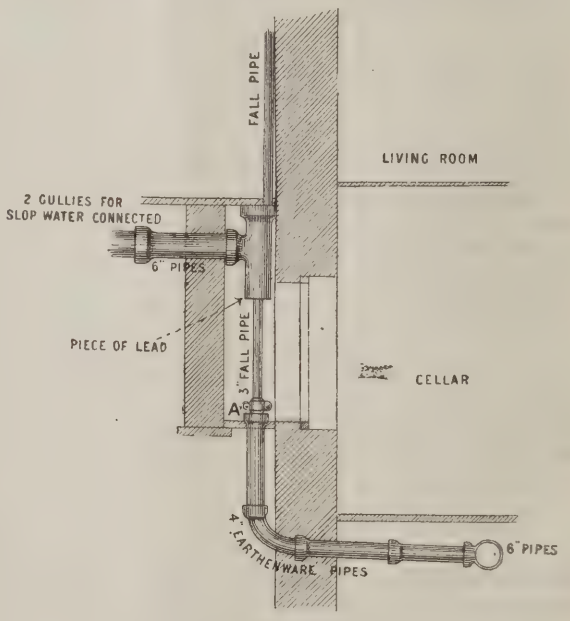
CORRESPONDENCE.

(We do not in any way hold ourselves responsible for opinions expressed by our correspondents.)

(To the Editor of The Sanitary Record.)

A CURIOSITY IN SANITARY DRAINAGE WORK.

Sir,—I beg to enclose you sketch of one of the curiosities of the Twentieth Century. In consequence of an outbreak of typhoid fever in a certain quarter of our district, the Surveyor and myself have been making a close inspection thereof; and I need not tell you of our surprise to find existing the somewhat mechanically



and curiously-constructed state of things, as indicated by the accompanying sketch, by which you will see that a 3in. cast iron fall pipe enters perpendicularly the end of a 6in. junction pipe, to which junction pipe are connected two 9in. gullies for slop water. The said junction pipe is joined to, and rests on the end of a 3in. cast iron pipe, supported inside most curiously by a piece of lead; then the bottom end of the 3in. pipe referred to is endowed with two lugs, which appear to act as a support to the whole fabric. The drain is then continued with 4in. earthenware pipes, of clay joints, and takes its course underneath the floors of a block of houses, back to back. Every joint of the whole thing admits of a

serious leakage. At the time of our visit the leakage from joint A was such that it percolated through the wall into the area, thence through the window on to the cellar floor. The terrible effects resulting from a condition of things of this sort need no comment. Neither were we surprised (on finding such an arrangement of things) to learn that the tenants were complaining and suffering from various physical ailments. — Yours faithfully, W. W.,

December 12th, 1900. Sanitary Inspector.

A CLEAN BILL OF HEALTH.

Sir,—I have read with interest Mr. Ernest Worrall's letter in your issue of the 10th inst., wherein he states that he believes it rare for an urban district to be entirely free from infectious disease for twelve months. He also draws attention to Penmaenmawr, in North Wales, with a resident population of 3500, which has attained this enviable distinction. Mr. Worrall inquires if any of your readers can of their own knowledge relate a like condition elsewhere. In reply I beg to submit particulars of Ramsey, Isle of Man, which shows an even better record. Resident population, 5000. Number of summer visitors, about 12,000. No case of infectious disease as defined by the Infectious Diseases (Notification) Act, 1889, notified as occurring within the town from August 27th, 1899, to November 26th, 1900. On the latter date a child was reported as suffering from scarlet fever.

A few years ago the conditions of Ramsey as a health resort were not good. Now they are excellent.—Yours faithfully, George W. Irwin.

Surveyor's Department, Ramsey,
Isle of Man, January 10th.

Public Works.

SEWERAGE.

Sanction has been obtained to a loan of £8000 for the Woodford sewerage works.

The Brierley Hill Council has decided to apply for a loan of about £32,000 for sewerage, sewage disposal, depôt, road-roller, &c.

The contract for Dalry drainage has been given to Mr. James Urquhart, Renwick. The contract price for the drainage alone amounts to £3018.

A Local Government Board inquiry has been held at Leyburn with reference to the application of the Rural District Council to borrow £5200 for sewerage purposes.

A circular letter from the Royal Commission on Sewage Disposal, asking to be furnished with results of experiments has been referred to the Newmarket Surveyor by the Urban Council.

The West Bromwich Corporation proposes borrowing £15,000 to carry out a scheme recommended by the Borough Surveyor (Mr. A. D. Greatorex) in his recent report on the bacterial treatment of sewage.

The Cockermouth Urban District Council is about to call for tenders for the proposed further surface drainage of the town, with a view to preventing the flooding of some parts of the town during heavy rains. The estimate is £198.

Col. Hepper, Local Government Board Inspector, held an inquiry at Conway last week with reference to an application by the Borough Corporation for power to borrow £770 for purposes of sewerage. It was explained that all the money had been expended, being excess expenditure on the Gyffin and Penybont sewers. The main item in the account submitted was for the outfall of the Gyffin sewer, which, owing to the objection of the County Council to allow the pipe to be laid through a county bridge, had to be laid in a different direction to that originally proposed, necessitating the placing of the outfall through a mud-bank

The Biddulph Urban District Council is contemplating a scheme of sewage disposal for its district.

A Local Government Board inquiry was held recently at Fulwell, concerning the application of the Rural District Council for sanction to borrow £300 for the sewerage works, and a proposal to execute certain works outside their district and in the borough of Sunderland. The Town Clerk of Sunderland appeared to oppose the latter proposal, and Mr. W. S. Hope represented the Fulwell Authority. The point in dispute is as to who shall own certain sewers if they are constructed. Evidence was taken, and the decision will be made known at a future date.

At a meeting of the District Committee of the Lower Ward of Lanarkshire held in Glasgow recently, in moving the adoption of the minutes of the joint Sub-committees of the County Council and the District Committee in connection with the proposal by the Corporation of Glasgow to obtain power to impose a sewage purification rate on two areas in the Lower Ward district, the Chairman said the only thing he did not like in the outlook was that in his experience Glasgow officials were apt to delay matters very much. He thought in the long run they would be able to come to a settlement that would be satisfactory to the Lower Ward.

A special meeting of the Walton-on-Naze Urban District Council was held last week, when the following resolutions were confirmed:—That the tender of Messrs. J. Moran and Son, for main sewerage and sewage disposal at £8950, be accepted; that application be made to the Local Government Board for sanction to borrow an additional sum of £2100, to carry out the scheme on particulars to be furnished by the engineers, Messrs. Beesley, Son, and Nichols; that Mr. Buckley, as recommended by the engineers, be appointed resident engineer during the works at a salary of four guineas a week, subject to one month's notice to discontinue on either side; that a Main Sewerage Committee be appointed, consisting of the chairmen of the Sea Defences, Sanitary and General Purposes, Building and Lighting, Finance and Licensing committees.

The published conclusions of the Sub-committee of the Bradford Sewage Committee, who went to Roubaix last year to inspect the Delattre process of grease extraction, are not very definite. The gist of them is that the Bradford sludge dealt with last time was not the most suitable in point of density, and hence the present proposal to send a somewhat different sludge. It must not be supposed that this process, if successful, will solve the whole sewage difficulty. At Esholt sludge, of course, would be produced. It is a question whether the Delattre invention is a really profitable method of dealing with the sludge. The grease recovered in the last experiment has been valued by a grease distiller at £9 a ton on the spot. Apparently the Sub-committee goes so far as to state that the Delattre method, while not one that could be economically used by individual firms, is likely to prove advantageous for dealing with a large quantity of suds producing over twenty tons of sludge a day.

The Royal Commission on Sewage Disposal recently visited the Reigate Corporation sewage works at Redhill to inspect the Candy-Caink revolving sprinkler system and polarite oxidation bacterial bed, which has been in highly successful operation there for over two years. Sir Michael Foster, M.P., F.R.S., Major-General Phipps Carey, Col. Harding, and Mr. J. J. Willis, the visiting members of the Commission, were met at Redhill by the Mayor, the Borough Engineer (Mr. W. H. Prescott), Mr. Frank Candy, and Mr. F. Pullen Candy, and made a careful investigation of the bacterial system, which, by means of the polarite oxidising aërobic bed fed in an intermittently continuous manner by the Candy-Caink revolving sprinkler, converts with about half an hour's treatment a very strong sewage containing tannery and brewery refuse into a first-class effluent, bright, odourless, and oxygenated. After the inspection the members of the Royal Commission adjourned to the Town Hall to take the evidence of Mr. Frank Candy, general manager of the International Purification Syndicate, 109, Victoria-street, Westminster, on the subject, and of the Borough Engineer (Mr. W. H. Prescott), who explained the entirely satisfactory working of the system and tendered analytical results showing an average purification of 97 per cent.

THE Uttoxeter Rural District Council has approved of the scheme by Messrs. Willcox and Raikes for the sewerage and sewage disposal of the parish of Denstone.

FOUR tenders, ranging from £2431 to £1693 have been received by the Plymouth Works Committee for the extension of the sewage outfall at Little Prince Rock. The Borough Surveyor's estimate of the cost was £1340, and he is to execute the work.

WATER.

THE Local Government Board has ordered a public inquiry to be held at the Guildhall, Westminster, on Monday, the 11th of next month, in regard to the new regulations made by the London water companies.

AT a special meeting of the Brynmawr Urban District Council, Mr. Haller, of the firm of Hallar and Machell, civil engineers, Dewsbury, submitted plans for improving the water supply of the town, at an estimated cost of £14,361 16s. 9d. After discussion, the further consideration of the scheme was deferred to a future special meeting of the Council.

AT a meeting of the Barrow Town Council recently the final steps with regard to the promotion of a Bill in Parliament for obtaining water from the river Duddon and Seathwaite Tarn were agreed to. It was also decided in response to a deputation from the Ulverston Rural District Council, whose district obtains its water supply from the Barrow Corporation, to supply water in bulk at 6d. per 1000 gallons, private consumers to be charged the same rate as those at Dalton.

LAST week a public meeting was held at Wolverhampton to consider the proposal of the Town Council to borrow £200,000 in connection with the Water Bill. Alderman Marston (chairman of the Water Committee), who described the scheme, said there was an idea that they could obtain water very cheaply by tapping the mains of the Birmingham scheme at Hagley, but the cost would amount to about £80,000 in works alone. The Town Clerk referred to the letter of Mr. Capel Cure, and said it was entirely a misapprehension to say that the Corporation was desirous of robbing people of water. There was no right in underground water. On the motion of the Mayor, a resolution was unanimously adopted approving of the Bill.

AT the last ordinary monthly meeting of the Thorne Urban Council, a subject in which a great amount of interest was centred was the water question, Mr. Fairbank, A.M.I.C.E., of London, attending. The County Council, in reply to a deputation, stated that if some definite steps were not taken by February 11th it would carry out a scheme and charge the cost to the district. It was stated that a fourth of the cost of the scheme would be charged upon land. All the members of the other parishes strongly deprecated the scheme, and meetings are being held in the various townships to protest against the action of the County Council. In the end Mr. Fairbank was instructed to submit a scheme, and also an estimate of the cost.

AT Haddington Town Council last week a very serious question was under special consideration. Some seven or eight years ago the Board introduced an augmentation water supply from Longyester, which is several miles south of the burgh, at a cost of between £6000 and £7000. The condition of the supply, especially in times of rainfall, has never been very satisfactory owing to discoloration and sediment, but only now has an alarming state of affairs been discovered in the fact that the pipes conveying the supply are in some places nearly closed with encrustation of a peculiarly hard character. Councillor Dr. Wallace James stated that he had analysed the encrustation and found it to consist of carbonate of iron, and probably the only remedy was at once to face the question of exposing the water for a considerable time in a settling pond. Councillor Dr. Ronaldson also strongly advocated dealing with the question on expert advice. After an animated discussion, in which the serious state of matters was fully admitted, the Board resolved to at once call in the services of Mr. Tait, C.E. The matter is naturally creating some dismay in the districts affected, as house pipes are found to be as seriously affected as the mains. The water comes from hill springs at the foot of the Lammermoors.

A MEETING of the Water Committee of the Aberdeen Town Council was held recently, when the attention of the Committee was drawn by the Convener to the present debt resting on the water supply undertaking, and he suggested that they should make some effort to wipe off this debt, at present £196,000. With the view of going in for a fresh scheme, which would be at considerable cost, it is thought advisable to raise the present rate by at least 1d. per £. In the meantime Mr. Cran, City Chamberlain, was asked to bring up a report on the matter. The feeling of the meeting was that a gradual increase on the present rate should be made. In all probability an increase of 1d. per £ will be made during the present year.

LAST week a largely-attended public meeting was held at the Mechanics' Institution, Stockport, in opposition to the proposal of the Corporation of Stockport to promote a Bill in Parliament for obtaining a further supply of water from the district of Kinder Scout, at an estimated cost of £820,000. The promoters of the Bill find that in ten years the limit of supply will have been reached, and are advised by Mr. Mansergh and other experts that the district of Kinder Scout offers the best source for meeting the future requirements of the rapidly growing district, the estimated cost of the new scheme being £820,000. It is proposed to construct reservoirs and other works only as they may be needed, thus spreading the outlay over about thirty years.

AT the St. Helens Water Committee meeting last week the Borough Water Engineer, Mr. J. J. Lockland, in a report stated that the present reservoirs at Brown Edge and Eccleston had a capacity of two million gallons and half a million gallons respectively. As the average daily consumption in summer or in time of frost was now 3½ millions per day, and had occasionally reached four millions the capacity of the reservoirs was thus equal to about two-thirds of one day's supply. This quantity, however, could not be regularly depended upon, as, owing to the demand for water being greater during the middle of the week than at the week end, there were frequent occasions on which the reservoirs were entirely empty. A breakdown at either the Knowsley, Kirkby, or Melling stations it would be possible to meet, by using the surplus power in reserve at one or more of the other stations, and this condition would probably continue for some years until the increasing demand for water should overtake the surplus quantity of supply. This surplus was that expected to be available at the Melling pumping station when regular pumping was commenced there. At the present time there was no surplus except the Collins Green water, which was not always surplus. The pumping main from Melling to Brown Edge conveyed the water pumped at Knowsley and Kirkby —2½ million gallons per day—and would be used for the supply from Melling until the total quantity should exceed four million gallons per day.

LIGHTING.

A PROVISIONAL Order for the extension of their mains and gasworks to Ruislip, Harefield, and Ickenham, is now being applied for by the Pinner Gas Company.

THE Nuneaton and Chilvers Urban District Council has decided that the electric works be extended at an outlay of £2500, the floors to be erected above the level of the recent flood.

THE Shoreditch Borough Council has accepted the tender of Messrs. Alton and Co., of Laurence Pountney-lane, for the supply of steam pipes, feed pumps, storage tank, and sundry ironwork to the electric lighting station.

THE Doune Gas Company having been in financial difficulties for a considerable time, a new company, under the title of the Doune Lighting Company, Limited, has been formed with the purpose of taking over the works and plant of the old company. The capital is £1000, divided into 2000 shares of 10s. each.

THE Urban Authorities of Bognor have obtained an Order from the Board of Trade for the purpose of lighting the town with electricity, and are now considering the advisability of organising a scheme for carrying out the work. The local gas company is putting forward an opposition scheme in favour of incandescent lamps.

Dumfries Town Council, having obtained a Provisional Order for the supply of electricity, has instructed a committee to consider the question of the appointment of an engineer to prepare a scheme, and to submit a name.

The Electric Lighting Committee has resolved to recommend the Leith Town Council to borrow money from time to time for electric lighting purposes, up to the limit already authorised by the Secretary for Scotland. There has already been borrowed £44,000, leaving £21,000 still available.

The manager of Troon Corporation gasworks reports that the quantity of gas made at the works from May 15th till December 31st, 1900, was 6,640,400 cubic feet, being an increase of 1,940,900 cubic feet as compared with the seven months in 1899, extending from June, when the works were municipalised, till December.

A Local Government Board inquiry was held at Wigan recently in regard to the Council's application to borrow £16,500 for electric light purposes. Sanction had been obtained to borrow £85,000, and the present application was to meet demands for current in the streets not touched at present. There was no opposition.

A Bill has been deposited for introduction into Parliament next session under which it is sought to incorporate a company under the name of "The Cleveland and Durham County Electric Power Company." The general purposes of the company are to produce and supply electrical energy or power in bulk to authorised distributors for lighting purposes, and to persons for power purposes only. The area within which the company may carry on business comprises the whole or portions of the unions of Easington, Sedgefield, Hartlepool, Stockton, Darlington, Teesdale, Auckland, Weardale, Lanchester, Durham, and the following unions or parts of unions in the North Riding of Yorkshire, viz., Middlesbrough, Guisborough, and Stokesley. Generating or power stations are proposed to be erected in the parishes of Witton-le-Wear, Lanchester, Consett, Hutton Henry, Woodham, Brotton, and Billingham.

The Board of Trade returns relating to the gas supply of the kingdom give some interesting particulars concerning the gas supply of the metropolis. There are five companies engaged in supplying London with gas light. The Gas Light and Coke Company, which is the largest of the five, and the largest in the world for that matter, supplies 22,000 million cubic feet of gas in a year; the South Metropolitan, which comes next, supplies 10,000 million cubic feet; and the other three—the Commercial, the Crystal Palace District, and the Wandsworth and Putney, to take them in their order of magnitude—supply about 4300 million cubic feet. The total output of the five companies amounts to about 36,300 million cubic feet, or over 26 per cent. of the total gas sales in the whole of the United Kingdom. Although the Wandsworth Company is the smallest of the five, it charges less for gas than any of the others. This company charges at the present time 2s. 4d. per thousand cubic feet, while the Gas Light and Coke charges 3s. 5d., the South Metropolitan 2s. 8d., the Commercial 3s., and the Crystal Palace and District 2s. 10d. per thousand cubic feet.

A Bill to confer further powers on the Shrewsbury Gas Light Company has been deposited for introduction into Parliament next session. Under this Bill the company propose "as from the 30th of June, 1901," to convert their existing £65,490 7½ per cent. consolidated ordinary stock into £98,235 "converted ordinary stock entitled to a uniform maximum dividend of 5 per cent." The converted stock is to be registered in the names of the shareholders who appear on the books of the company on the date specified in the proportion of £150 for every £100 of the existing stock. The company also seek power to raise £80,000 additional 5 per cent. capital "to meet the increasing demand for gas within their area of supply." The new capital is to be offered by auction or tender, and any sum of money received by way of premium "shall be expended in extending or improving the works of the company or in paying off money owing on mortgage." Upon the converted capital of £98,235 the company ask for power to borrow "forthwith after the passing of this Act," any sums not exceeding £26,666, including the sum of £16,000 already borrowed, and upon the additional capital of £80,000 borrowing powers are sought to be exercised to the extent of one-third of the amount raised from time to time.

The Bermondsey Borough Council has decided to accept the tender of Messrs. Crampton and Co. for supplying and erecting arc lamp columns and arc and incandescent lamps at £2595.

At its last meeting the St. Alban's Council adopted the report of a Committee recommending the introduction of electric lamps for lighting the streets. It is probable that the local gas company will construct the works at a cost of £20,000.

Further particulars are published in the *Gas World* of the huge scheme for the supply of fuel gas in South Staffordshire and East Worcestershire for which the sanction of Parliament is to be sought in the coming session. The capital proposed is £1,000,000, with borrowing powers to the extent of one-third of the paid-up capital. The district sought to be exploited includes the following boroughs and urban or rural localities:—Dudley, Smethwick, Walsall, Wednesbury, West Bromwich, Wolverhampton, Amblecote, Bilston, Brierley Hill, Coseley, Darlaston, Handsworth, Heathtown, Lye, and Wollescote, Oldbury, Perry Barr, Quarry Bank, Rowley Regis, Sedgeley, Short Heath, Stourbridge, Tipton, Wednesfield, Willenhall, Halesowen (Rural), Kingswinford (Rural), and Walsall (Rural). It is intended that the gas shall be used for motive power and for heating purposes, "or for any other purpose to which such gas can be applied, but not for illumination."

In further reference to the "Electric Lighting Boards" system of electric lighting, the new company which has lately been formed to exploit the work under the title "Electric Lighting Boards (British Manufacturing Company) Limited" has made a most effective start by supplying the large quantities of patent strip used in the great Palace of Glass scene in the Drury-lane pantomime, and in the marvellous Ball Room scene at the Hippodrome, which have created such sensations. Effects of such brilliance would have formerly been quite outside practical politics on account of expense. At the Hippodrome the British Electric and Telephone Company applied the new strips, and at Drury-lane Messrs Salviati and Jesurum did the installation work, in both cases in consultation with Mr. Julian Halford, the company's manager, and inventor of several of the accessories in connection with the system. These two very comprehensive applications under particularly difficult circumstances and at very short notice again showed the great use of the system where time and economy are of importance, quite irrespective of any question regarding the possibility of a rapid variation in the position of the lights. Although the company's system has only been before the public for a few short weeks, the manner in which it has been received has already led the company to extend its factory accommodation to some large premises at King's Cross, whilst retaining its showrooms and West End workshops at 18, Dean-street, Soho.

The members of the Longton Town Council paid a visit to the gasworks last week, to inspect the water-gas plant recently erected. The manager (Mr. W. Langford) conducted the visitors through the works, and much interest was taken in the appearance and working of the water-gas plant, which occupies about one-third of the old retort-house. The works are so designed that space is left for the future extension of the new retort-house, and an additional set of water-gas plant when required; meantime the old retort-house will supply the long-felt want of a coal store, having a railway on each side for delivery, and being close to hoppers for supplying coal to retort-charging machinery. The boiler-house is built at the end of the old retort-house, and is supplied with two Lancashire boilers, 27ft. by 7½ft., fitted with Hopkinson's mounts and Wilton's forced draught furnaces, so that breeze dust may be used for firing. During the last six months a new 18in. main has been laid for the town supply from the works to the Market-square, in lieu of the 12in., which was inadequate, and on the works the old 12in. crude gas main from the new retort-house to condensers has been replaced by an 18in., and the gas connections for the new retort stack have been arranged so as to draw off the gas from each end instead of only one end as formerly, and each bed of the new house has been reset with new retorts. During the last ten years the output of gas at the Longton Corporation gasworks has increased 70 per cent. In 1896 the output was 102,368,000 cubic feet, as against 151,306,000 last year, being an increase of 48 per cent. in four years.

GENERAL.

THE King's Norton Urban District Council has decided to erect public baths.

THE Sunderland Town Council has decided to spend £27,000 in extending its tramways.

THE accounts of the Hospital Saturday Fund are now closed. The total receipts for the year were £20,222, as against £20,002 in 1899.

THE Stroud Joint Hospital Board is expecting the sanction of the Local Government Board to a loan for the purchase of a site at Hamwell Leaze for an infectious diseases hospital.

FOLLOWING the lead of other cities in the country, the members of the Health Committee of the Bradford Corporation are considering a proposal to establish a pathological and bacteriological laboratory.

THE Hongkong Sanitary Board has refused, on account of the expense, to have a cinerator there to burn up the carcases of diseased cattle and pigs. The plan of dumping such refuse on the other side of the harbour found favour.

MR. W. A. DUCAT held an inquiry at Dudley last week in reference to the application of the Town Council for the sanction of the Local Government Board to a loan of £2225 for street paving, and £460 for the purchase of a 15-ton steam roller.

WE are informed that the Southwark Borough Council has appointed three women Sanitary Inspectors at salaries of £160, £130, and £120 per annum, and has also decided to engage two women as Inspectors of Infectious Diseases at salaries of £110, rising to £160.

THE Hull Municipal Crematorium was recently inaugurated by the cremation of the body of a lady. The body was taken from Leicester. It was stated that the lady had seen a notice of the first municipal crematorium, and had expressed a wish that her body should be taken to Hull and cremated.

THE London County Council having decided to run a service of electric trams on Denmark-hill, has also deemed it necessary to widen that thoroughfare. It has accordingly approached the Lambeth Borough Council with a view to securing from that body one-third of the total cost of the improvement.

THE Lord Mayor of Leeds recently presided at the Leeds Town Hall over a meeting in connection with a scheme for the open-air cure of consumption. The open-air treatment at Farnley was highly commended, and it was reported that during the past fifteen months eighteen patients had been successfully treated there. It was proposed to establish a permanent sanatorium near Selby, on the Gatesforth estate, which has been purchased by the Leeds Corporation. The report of the Committee was adopted, on the motion of the Lord Mayor, seconded by Sir James Kitson.

AT a recent meeting of the Blore Heath Rural District Council held at Market Drayton, with respect to the recent outbreak of enteric fever at the village of Aston, the Medical Officer for the county (Dr. Reid) presented his report, which stated that he had inspected the houses in which cases of enteric fever had occurred. Most of the cottages in the village resembled those usually met with in old agricultural villages, although the conditions of some of them necessitated their being placed even lower in the scale, and it was questionable whether any measure short of demolition would meet the case. Samples of water from six of the wells had been analysed, and these were all seriously contaminated, one being little better than sewage effluent. Five of the cases which occurred in the village had a water supply in common, which upon analysis proved to be the worst sample of the lot. The surroundings generally were such that even had the water supply been satisfactory the outbreak might, with ample reason, have been attributed to the highly polluted state of the ground arising from the absence of proper drainage. The Chairman of the Council stated that on behalf of the owners an expert should be employed, and see what could be done to remedy matters, and the question was eventually adjourned until the next meeting, and the Clerk in the meantime was instructed to write to the several occupiers forbidding the use of the water for domestic purposes.

THE Grays Urban District Council is about to erect workmen's cottages, at a cost of £6400.

A LOCAL Government Board inquiry has been held at Bootle into the application of the Town Council for sanction to borrow £29,200 for fire-station purposes, £4300 for the provision of public baths and a gymnasium, £3645 for police-station purposes, £2300 for provision of a library and reading-room, £2020 for the purposes of a public assembly-room, £1764 for the purposes of street improvement.

AT a meeting of the Sanitary Committee of the Dundee Town Council last week a circular was submitted from the Local Government Board on the subject of arsenic in beer. It stated that no cases had come to the knowledge of the Board, either as to the occurrence of similar illnesses as those in England or the presence of arsenic in beer in Scotland. Indeed, they were aware that the analysis instituted had yielded negative results. The Board called attention to the danger of the presence of arsenic and glucose in the manufacture of preserves, sweetmeats, and the like. The Sanitary Inspector was directed to procure samples of these for the purpose of analysis and report.

PERSONAL.

MR. S. J. JAMES LOGIN has been appointed Sanitary Inspector for Whitland.

DR. ROBERTS has been appointed Medical Officer for Deptford, at a salary of £225.

MR. C. H. SANDERSON has been appointed Assistant Surveyor for the rural district of Clutton.

DR. J. T. MACNAMARA has been appointed Medical Officer for the Ladywell Workhouse, St. Olaves.

MR. BARRAS has been reappointed Surveyor and Inspector of Nuisances for Doncaster for six months.

THE salary of Dr. Dingle, as Medical Officer for Middlesbrough, will be increased £50 per annum from April next.

DR. D. L. THOMAS, a native of Newcastle Emlyn, has been appointed chief Medical Officer of Health for the borough of Stepney.

DR. JOHN M. MARTIN has been appointed Medical Officer of Health for Stroud, in room of Dr. Thomas Partridge, resigned.

MR. O. E. WINTER has been appointed Borough Surveyor for Poplar, and Mr. Blackman has been appointed Borough Engineer.

MR. R. L. LEGATE has been reappointed Medical Officer of Health for the Christchurch urban sanitary district for one year.

DR. CHARLES ROBERTS, Medical Officer for Uxbridge, died suddenly at Victoria Station on Thursday last from heart disease.

THE Local Government Board has sanctioned the reappointment of Dr. Kenwood as Medical Officer for Finchley for one year.

MR. W. WOOD, of Leeds, has been appointed Sanitary Superintendent for Hull, at a salary of £150 per annum, to increase to £180.

MR. A. T. MILLS, Sanitary Inspector to the borough of Bethnal Green, has been appointed by the Hornsey District Council as Building Inspector.

DR. CULLEN has been unanimously reappointed Medical Officer for the Castleknock dispensary district, under the North Dublin Board of Guardians.

MR. ARTHUR H. SHAW, of Harrow, has been appointed the resident Electrical Engineer to the Ilford Council, at £300 per annum for three years.

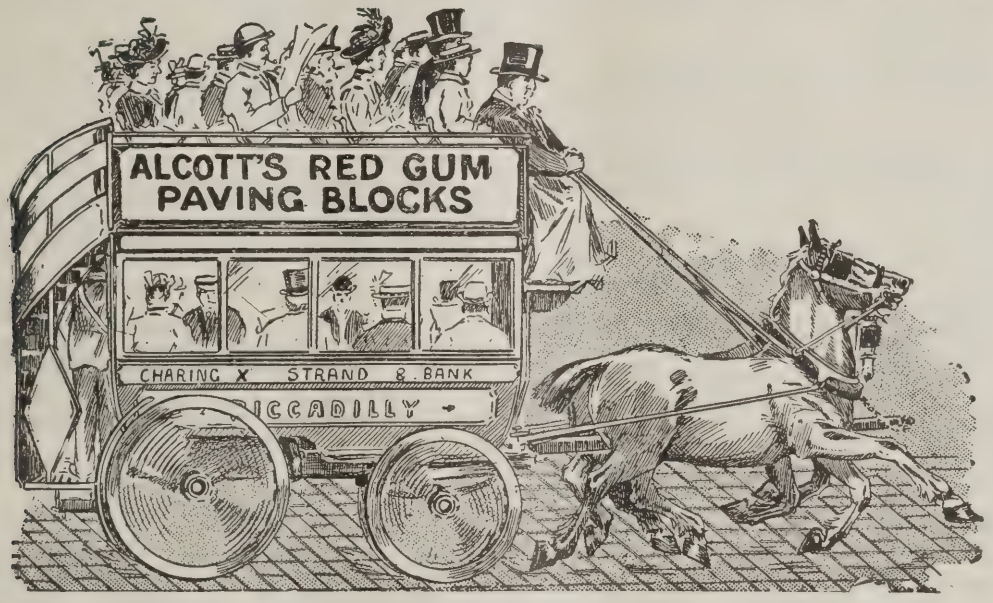
DR. ED. LONG JACOB has been appointed Medical Officer of Health for the urban and rural sanitary districts of Reigate, at a salary of £150 per annum.

MR. P. G. KILLICK, late Surveyor to the Clerkenwell Vestry, has been appointed the Finsbury Borough Surveyor, with Mr. Harley Heckford, late Surveyor of the St. Luke's Vestry, as his deputy, the respective salaries to be £400 and £350 per annum, with no superannuation or compensation for loss of office.

Alcott's Red Gum

Is ABSOLUTELY the

BEST WOOD FOR STREET PAVING.



THE "BUS-HORSE" BRAND.

ALCOTT'S RED GUM is a durable Paving.
ALCOTT'S RED GUM is not Slippery.
ALCOTT'S RED GUM is Noiseless.
ALCOTT'S RED GUM does not Swell nor Shrink.
ALCOTT'S RED GUM wears Smooth and Even.
ALCOTT'S RED GUM does not wear into ruts; does not require gravel; is easily cleansed and, being non-porous, is sanitary.

For Particulars, &c., apply to

EDWARD ALCOTT,

65 and 67, Millbank Street, Westminster,

LONDON, S.W.

Dr. G. D. Jenkins, Assistant Medical Officer, Bethnal Green, has been appointed Medical Officer for the Rhondda Valley urban district, at a salary of £500 a year.

Mr. James Weatheritt has been appointed Inspector under the Southwark Town Council to carry out the provisions of the Sale of Food and Drugs Acts, at £225 per annum.

The Local Government Board has sanctioned the appointment of Dr. John Blanchfield Keoghias as Medical Officer of the Barrow dispensary district, at a salary of £100 per annum.

The Local Government Board has sanctioned the re-appointment of Mr. Bernard Godfrey as Surveyor and Sanitary Inspector for Rotherham rural district for the year ending October, 1901.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2067.—Separate Drainage for Soil and Surface Water.—"Building Surveyor" writes:—"I note in your issue of the 4th inst., under "Cross-Table Chat," a paragraph referring to the approval by the Local Government Board of bye-laws relating to the separate system of drainage for soil and surface water. I should be glad if you would give me the name of any Authority who have had bye-laws approved with these clauses inserted."

Answer.—We find on making inquiries in official quarters that the Urban District Council of Carshalton, Surrey, have obtained an excellent series of Model Bye-laws, under which separate drainage for soil and surface water may be enforced. The same Authority's bye-laws, we understand, also contain provisions prescribing the methods of drainage of existing houses. We think it is very probable that if a courteous application—enclosing twopence in stamps for postage—were made to the Clerk or to the Surveyor to the Council, either of them would kindly furnish a copy of the said bye-laws.

2068.—Sewage Disposal: Leeds Report: Analysis of Sewage.—"Sewage Works Manager" writes:—(1) "In 'Cross-Table Chat' a few weeks ago, reference was made to the joint report of Colonel Harding and Mr. Hewson on the recent experiments at Leeds, in the bacterial treatment of sewage. Is the report obtainable from any printer, or was it issued for the Council only? I have made inquiries, but no one seems to know anything about it. Will you kindly state whether this report can be purchased? (2) Can you also inform me where the Massachusetts report is obtainable in this country, as I should much like to see it? (3) In the pamphlet on 'The Bacterial Treatment of Sewage,' by Mr. Thudichum, he states that with practice any sewage works manager might be able to analyse the sewage and effluents. Is there any book published that gives the information? What apparatus is required for the purpose? I am sorry to trouble you so much, but will endeavour to repay you by recommending your valuable journal to friends and others."

Answer.—The Leeds report on the experiments in the bacterial treatment of sewage, conducted under the supervision of Colonel Harding and Mr. Hewson, was printed for the use of the members of the Corporation, and has not been published for sale. The most important parts of the report, however, were reprinted in our contemporary, the *Contract Journal*, published at 139-140, Salisbury-court, Fleet-street, London, E.C., price 6½d. weekly, post free. The numbers containing same will be obtainable on application. The querist will probably find the recently-issued third report of the London County Council on "The Bacterial Treatment of Crude Sewage," by Professor Frank Clowes and Dr. Houston, price 2s. 3d., post free, from the office of Sanitary Record, valuable and interesting. (2) These reports are not, so far as we are aware, published for sale. In the quarterly *Journal* of the Sanitary Institute for April, 1896, price 2s. 8d., post free, will be found an admirable paper on "The Lessons to be Learnt from the Experimental Investigations by the State Board of Health of Massachusetts upon the Purification of Sewage," by Captain Sir Douglas Galton, R.E., which we can heartily recommend for careful perusal. (3) In Dibdin's "Purification of Sewage and Water," price 21s., post free, from this office, will be found information as to how to analyse sewage effluents, and a list of apparatus necessary for the purpose. It is needful, however, to point out that Mr. Thudichum advocates, in his excellent little book "The Bacterial Purification of Sewage," price 1s. 3d., only a comparatively simple, and yet valuable, method of estimating the amount of chlorides present in sewage, which may be acquired by any sewage works manager. This process must not be looked upon as a substitution for a proper chemical analysis, but as a means of testing the quality of the effluents. Chemical apparatus and solutions and tests may be obtained from Messrs. Francis Sutton and Co., chemists, Norwich. We appreciate our correspondent's recognition of the value of this journal, and his kind promise to recommend it to his friends. Our correspondents generally can greatly assist us and reciprocate our efforts on their behalf by recommending the journal to other officials, Councillors, and persons interested in sanitary work. Specimen copies for circulation among such will be sent post free on application.

2069.—Local Surveyors: Examinations and Qualifications for.—"Sergeant" writes:—"Will you kindly inform me what are the qualifications necessary for the post of Local Surveyor? I understand that there are examinations held by different bodies, some of which are more difficult than others. Please advise which is the easiest examination to qualify for Local Surveyor; and also what books to study; the periods and places at which examinations are held, and by what body? I already possess the Certificate of the Sanitary Institute for Inspectors.

Answer.—The querist is advised to obtain Boulnois's "Municipal and Sanitary Engineer's Handbook," price 15s., wherein he will find the qualifications and duties of a Local Surveyor ably and succinctly prescribed. The book is indispensable to all persons who desire to obtain the position of a Local Surveyor.

STANLEY
Government Contractors.
Makers of Mathematical, Drawing and Surveying Instruments of every Description.
Gold Medals at the Great Exhibitions. Catalogues post free.

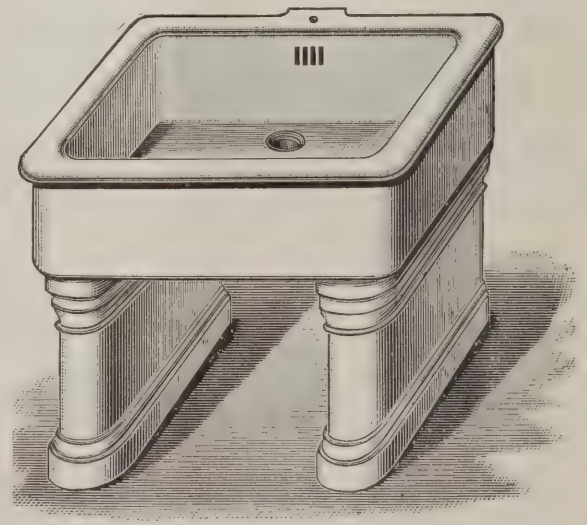
Great Turnstile, Holborn, London, W.C.

CRAIG'S WHITE GLAZED FIRE-CLAY SINKS
On White Glazed Fire-Clay Supports.
In appearance nearly equal to Porcelain, which they greatly excel in strength and durability. Admirably adapted for use in Kitchens, Sculleries, Butlers' Pantries, Laboratories, &c. Extensively used in houses of the better class, and in many important buildings throughout the country during the last thirty years.
Adopted by H. M. Board of Works, H.M. Commissioners of Prisons, &c.
Awarded First Prize Medal by the Sanitary Institute of Great Britain



J. & M. CRAIG, Ltd., KILMARNOCK

A SUGGESTED METHOD OF PREVENTING WATER-BORNE ENTERIC FEVER AMONGST ARMIES IN THE FIELD.*

By Louis Parkes, M.D., D.P.H., Medical Officer of Health for Chelsea, and Samuel Rideal, D.Sc., F.I.C.

Everyone is aware that our troops in the South African campaign have suffered very severely from enteric fever—notably in the Bloemfontein outbreak following Lord Roberts' march from Paardeberg. Numerous questions arise in connection with this outbreak, and with the very general prevalence of enteric fever during the campaign, which we may hope to see answered when the whole conduct of the war has been under review. In the meantime, these questions may be briefly summarised as follows :—

(1) Has the number of cases of enteric fever, proportional to troops employed, exceeded that characterising other campaigns in similar climates, with similar disadvantageous sanitary surroundings?

(2) Was the likelihood of enteric fever becoming epidemic amongst the troops foreseen by the military authorities?

(3) Were the best practicable and available means taken to safeguard the army, both in stationary camps and when on the march?

The answers to these questions will be awaited with immense interest, not only by the medical profession, but by nearly every person of intelligence who has followed the various incidents of the war.

There can hardly be any doubt on the point as to whether the infection of enteric fever was introduced into South Africa by British troops, or was conveyed to the latter from pre-existing sources in the country which was the seat of warlike operations. Enteric fever is endemic in South Africa, and prevails in many parts of the country every summer season. Whereas the troops leaving England, and probably those also from India and the British Colonies, were subjected to medical inspection before embarkation, and were no doubt very free from the disease on arrival at the Cape.

It is evident, therefore, that the British Imperial forces must have become infected in South Africa by local conditions, and did not carry the disease with them from their homes. Again, it seems highly probable, from what is known of the mode of spread of enteric fever, that the first cases amongst the troops arose from the consumption of water infected with the enteric virus, derived either from the civil population with whom the troops were brought into contact, or more probably from the Boer combatants, amongst whom it is generally supposed the disease was present from their first taking the field.

Once established amongst our own forces by means of infected water, it is quite likely that the subsequent spread was largely due to personal infection from the necessarily prevailing conditions of camp and veldt life —that is to say, common latrines, uncovered and undisinfected excreta, flies carrying contagion from the excreta to the food, dust storms depositing infective material on food and drink, absence of isolation of the sick, and the want of proper hospital appliances.

Inasmuch as troops on the march are always very careful to choose camping grounds which have not been previously in use, unless strategical reasons render such a course necessary, whereas they are often dependent for their water supply on sources which have been already defiled, either by the enemy or by advance columns of their own side, the assumption would appear to be warranted that if it were possible to render all water used in drinking by the troops innocuous, there would be general development of enteric fever on a large scale, sufficient to cripple an army, such as has been the case during the present campaign.

We await information as to what has been the practical experience with the South African army of the attempts made to sterilise water for the use of troops, either by boiling or by filtration. Even now, however, it is almost safe to assume that such methods can only have a practical application at stationary camps, and are impossible of attainment during the rapid marches and swift changes of position that war conducted on modern methods necessitates.

The feature of the wars of the future will probably be, as the result of recent experience, the employment of highly mobile forces. Troops, both foot and mounted, will be expected to move with great rapidity, and with very short intervals for rest; transport will be reduced to a minimum, and the filtration or boiling of water for troops on the march will be impracticable.

BOILING AND FILTRATION IMPRACTICABLE.

We have not yet heard the full medical details of the march of Lord Roberts' army from the Modder to Bloemfontein, but it seems certain that the infantry outmarched both their regimental and brigade transport, and were dependent for their drinking water upon the polluted streams or dams which they crossed, and which in many instances had been already grossly fouled by the retreating enemy.

Even if filters or boiling apparatus can be made to accompany a rapidly-moving column, it is very doubtful if men parched by long marches performed under a fiery sun and in clouds of dust can be restrained from slaking their thirst as soon as they arrive at water. It is more than can be expected from human nature under such circumstances to await the tedious delivery of the sterilising filter, or the cooling of the water that has been heated to a boiling temperature. The agonies of thirst are intense, and at the time far outweigh any such considerations as those of prospective illness from the consumption of a germ-tainted water.

Failing, therefore, the sterilisation of water boiling or filtration, is there any substance which can be added to water which will destroy the virulence or inhibit the growth of the *Bacillus typhosus*, whilst not rendering the water unpalatable or injurious to the health of the consumer? It is evident that the ordinary poisonous—or even non-poisonous—disinfectants are inadmissible for this purpose, as if added to the water in quantity sufficient to exert a germicidal action they would undoubtedly prove harmful to the consumer, if not at first, at any rate after repeated doses.

CHEMICAL PROCESS.

There are other substances, however, which might be expected to prove beneficial as regards their effect upon *Bacillus typhosus*, whilst not harmful to the consumer. Such are the dilute mineral acids—dilute sulphuric acid, B.P., and dilute nitro-hydrochloric acid, B.P., and the organic acids, citric, and tartaric, which are largely used in the manufacture of lemonade. Other substances with which we have experimented are acid bisulphate of soda, and acid phosphate of soda, and sulpho-vinate of soda.

All of these are bodies of which the human system is tolerant, whilst in the proportions which we have found to be required (after contact of from fifteen to thirty minutes) to inhibit the growth and activity of *Bacillus typhosus*, they are quite palatable, imparting a sub-acid flavouring, which is agreeable to the taste and would materially aid in quenching thirst.

SULPHURIC ACID.

As regards previous investigation of this subject sulphuric acid has been shown by A. Stutzer to be fatal to cholera bacilli in fifteen minutes, when used in the

* A paper read before Epidemiological Society, Friday, January 18th, 1901.

proportion of five parts to 100,000 of water (0·05 per cent. solution). Hydrochloric and nitric acids are probably equally efficacious, but it does not appear that any sufficiently detailed experiments have been made on the destructibility of the organism of enteric fever.

CITRIC ACID.

Dr. Christmas, in 1892, showed that citric acid, although fatal to the cholera bacillus when used in the proportion of eight parts in 10,000 parts, did not destroy the bacillus of typhoid in a less strength than one in 1000.

Reinsch states that 0·028 per cent. of tartaric acid in water "began to diminish the bacteria, and 0·2 per cent. killed them" (*Centrabl. f. Bakteriol*, 1891, vol. x., page 415). Tartaric acid has also been employed in filters, and its use has recently been suggested in Italy for sterilising salads before consumption.

Schumberg's bromine process for purifying water (Pfuhl, *Zeits. f. Hygiene*, 1900, 53) is specially advocated for army purposes, for sterilising water in the tropics, for use on ship board, and in the case of waters derived from suspected or infected harbours. It consists in adding 0·06 grain of free bromine, dissolved in potassium bromide solution, for every litre of water. The excess of bromine is removed by adding an equivalent quantity of ammonia, which renders the water palatable. Pfuhl states that the small quantity of bromide present is entirely devoid of the possibility of injury to health, and that the taste can scarcely be distinguished from that of the water before treatment.

In July, 1897, Braithwaite suggested the use of a mixture of bromide and bromate, added to the water in the form of a tabloid, to be followed by a tabloid of acid sulphate of soda or potash. May, Baker, and Co. sell a similar mixture under the name of "bromidine," but it has not a very large sale. The quantity of bromine recommended was that obtained from two grains of bromide, or about one grain per quart, which gives only about one part in 17,500 of water. This quantity is much smaller than the authorities recommend for sterilisation. About one part in 2000 seems to be a safe quantity to use, or nine times the amount suggested above; and this would render the quantity of bromide finally formed and remaining in the water rater too high for dietetic use.

The tabular statement of Experiment I. shows that the substances therein given, when used in sufficient strength and allowed to remain for a sufficient time in contact with the infected water, are capable of preventing any further growth of *Bacillus typhosus*, when some of the infected water is agar plated.

In the case of tartaric, citric, and nitro-hydrochloric acids, it does not appear that anything less than the maximum B.P. dose per pint of water is efficient to sterilise, if the contact is not to last longer than fifteen minutes. Half the maximum dose (ten grains) per pint is inefficient in the case of citric and tartaric acids after fifteen minutes contact, whilst the minimum dose (five grains) per pint of citric acid has no effect after twenty-four hours' contact; and in the case of tartaric acid, the minimum dose did not completely sterilise after the same period. Of the two, tartaric acid appears to be the most potent in its destructive action upon *Bacillus typhosus*.

The pint has been taken as a standard, as this is the quantity of water which a man might be expected to drink off at once: one gramme to the pint is equivalent to 1 in 568.

As regards the dilute acids, nitro-hydrochloric and sulphuric, the former appears to be more efficient than the latter; but no further experiments were made with them, as it was considered essential that the substance to be carried by individual soldiers in the field should be a solid, which could be made up into small tabloids, and not a liquid, which would have to be carried in a bottle, and be measured out with some exactitude when required for the purpose of sterilising the water to be used for drinking.

* The acidity of this solution is equal to 4·8 c.c. N_{10} Na OH per litre, and the corresponding H_2 804 solution 5·8.

SOLIDS NECESSARY.

Acid sodium bisulphate is not a B.P. medicinal substance. It probably has no purgative effect, as the astringent properties of its free sulphuric acid would tend to counteract any laxative action of the sodium sulphate. The minimum purgative dose of sodium sulphate is a quarter of an ounce, and as we only suggest the use of fifteen and a-half grains of the bisulphate to every pint of water, a man would have to drink seven pints of water before a quarter of an ounce of a salt, not known to be purgative, would be taken. Even if this quantity of water was drunk in a day, there is no evidence that a quarter of an ounce of the bisulphate would exert any harmful effect.

SODIUM BISULPHATE.

There is evidence from Table I. that the *Bacillus typhosus* is killed by only five minutes' contact with sodium bisulphate in the proportion of one gramme (fifteen and a-half grains) per pint of infected water; but in our opinion it is better that contact should be made for fifteen minutes, in order that sterility may be ensured.

(*To be continued.*)

AN anonymous donor has, through Dr. Macormack, presented a cheque for £100 to the funds of the Newport Hospital, in order to equip it with a complete set of Röntgen rays apparatus.

SEWAGE DISPOSAL IN CALCUTTA.

By A. E. Silk,

Member of the Institute of Civil Engineers, Member of the Sanitary Institute, Sanitary Engineer, Bengal.

(*Concluded from page* 23.)

CHAPTER IV.—Chemical Examinations.

The effluents and filtrates were examined periodically for (*a*) total suspended matter, (*b*) oxygen absorbed in four hours at 80 deg Fah., (*c*) albuminoid ammonia, (*d*) nitrogen as nitrites, (*e*) nitrogen as nitrates, (*f*) chlorine, the object being to compare the results obtained with this experiment with those recorded in England. Soon after the experiment was started and the first few chemical analyses had been made, it became evident that such a comparison was not possible by reason of the difference in the strength of the sewage dealt with. In England sewage amounts to as much as 30 gallons per head, consisting of bath and kitchen water, and fæcal matter and urine from water-closets mixed with from two to three gallons of water per head, the usual water-closet flush; in this experiment the sewage to be dealt with, as already explained, consisted of fæcal matter and urine mixed with only three gallons of water per head, and for a short period only half a gallon of water per head was used. It is submitted therefore that the sewage dealt with in this experiment was at least six times, if not more, as strong as the sewage disposed of in England. The results of the chemical analyses are recorded in the tables on this and next page, for comparison with English results, but with those that may be obtained hereafter in India. The analyses were made in the laboratory of the Chemical Examiner for Bengal from samples taken personally by the author, and as little time as possible was allowed to elapse between the taking of the sample and its analysis; it would have been better and more scientific if the samples could have been taken at more frequent and more regular intervals, but this was impossible owing to the author's frequent absence on tour and to the former Chemical Examiner declaring his inability to deal with so many samples with the establishment at his command were worse than crude English sewage; but in spite of what analyses may show, the fact remains that the filtrates have never caused any nuisance, nor have they shown the slightest sign of putrefaction. Towards the end of last year the experts' report on the treatment of Manchester sewage was published, and the following description of the incubator test is taken from it:—"A very valuable indication of the degree of impurity of any sewage or effluent is afforded by the so-called incubator test. To carry out this test a determination is first made of the oxygen absorbed from potassium permanganate by the sample in three minutes. A bottle is then completely filled with the sample, and closed and placed in the incubator at 80 deg. Fah. for six or seven days. The three minutes' oxygen absorption is then again determined. If any putrefaction has taken place, the oxygen absorbed in three minutes will exhibit a decided increase in amount owing to the more ready oxidisability of the products of putrefaction, such as sulphuretted hydrogen, &c. On the other hand, if the sample keeps sweet, the three minutes' oxygen absorption remains practically unchanged after incubation, or there will be a slight decrease owing to the slight oxidation of the impurities which has taken place during the period of incubation at the expense of the nitrate or dissolved air present in the sample."

The incubation test was applied to all samples taken during the present year with the following results:—

Date.	Septic tank.		Slag filter.		Cinder filter		Scott-Moncrieff filter.

Chlorine...	5·00	Not examined.					—	30·0	31·0
	Water used, 3 gallons per head.						Water used, ½ gallon per head.		

A series of analyses taken during April and June, 1897, at the Exeter septic tank, gave the following average results:—

	Crude sewage.	Effluent from septic tank.	Filtrate. Practically.
Total suspended matter	3·5	15·4	Nil.
Oxygen absorbed in four hours at 80 deg. Fah....	2·89	2·01	0·55
Albuminoid ammonia...	0·30	0·25	0·11
Nitrogen as nitrites	—	—	0·36
Nitrogen as nitrates	—	—	0·50
Chlorine...	7·1	7·3	7·3

It would therefore appear that, from a chemical point of view, even the filtrates produced in this experiment These samples were taken when the experiment was under its most severe test, and only half a gallon of water per head was being used. The results may be considered to be eminently satisfactory, for in this case we have the actual absence of putrefaction or any sign of putrefaction confirmed by a chemical test.

CHAPTER V.—Conclusions.

It must not be concluded from the results of this single experiment described in the preceding chapters that the problem of the disposal of Indian sewage has been completely solved. It is true that the sewage of most Indian municipalities and cantonments is of a fairly uniform quality and consistency, excluding those towns, of course, where there is a water-carriage system of sewerage; and that a system of sewage disposal that suits one

town will probably be satisfactory in another. But it is rather doubtful whether sewage treated in this experiment was actually as strong, even when each stool was mixed with only half a gallon of water per head, as the sewage that will have to be dealt with in municipalities and cantonments. All that can be claimed for this experiment is that the fæcal matter of 220 people per day has been disposed of satisfactorily and with absolutely no nuisance, and that this system of disposal has been shown to be capable of dealing with a sewage consisting of half a gallon of water to every stool. It is hoped too that this experiment has indicated the lines on which future experiments may be carried out, and in this chapter endeavours will be made to make a few suggestions, based on the experiences of this experiment, for the guidance of those who are willing to make further attempts for the solution of the problem of sewage disposal in India.

In England it is found that a septic tank can break down the organic matter in sewage into simple compounds in about twenty-four hours, but, although putrefaction takes place so much more rapidly in this country and more especially in Bengal on account of the damp heat, it is probable that from seven to ten days must be allowed for, when calculating the size of the septic tank. In England, although there are hours of maximum flow of sewage, the sewage is constantly flowing; in India, however, all the night-soil has to be collected and removed in the early morning, and there is practically no collection going on during the rest of the day. This may mean that a whole day's produce of sewage would have to be rushed into the septic tank in a few hours. It is, however, one of the essential points that the liquid in the tank should not be violently disturbed, and consequently that the rise and fall of the surface of the liquid should be as small as possible; this will keep the scum, which is the breeding and collecting ground of the anaërobic microbes, fairly intact. The work of the anaërobic microbes was completely paralysed by violently shaking a bottle containing a sample of crude sewage which up till then had been undergoing the breaking-up process in a perfectly normal manner. The arrangements therefore for introducing the sewage and withdrawing the effluent must be made in accordance with these conditions. The greatest possible care must be taken in commencing work with a septic tank, and it must be remembered that to start off with the full daily supply of night-soil will mean disaster. Probably the best procedure is to fill the tank full of water and then start feeding in night-soil and drawing off the liquid, but the feeding must be done with gradually increasing quantities, say one-eighth of the full supply for a week, then a quarter for the next week, and so on. It has already been stated that the accumulation of the gases of putrefaction in the septic tank did not give any trouble, and also that perhaps provision for drawing off the gases might prevent the evolution of sulphuretted hydrogen at the outlet; any valve that is provided must be of the non-return pattern, so as to prevent air being sucked into the tank as the water-level therein falls.

The effluent as it leaves the septic tank is devoid of all oxygen in solution; every opportunity should therefore be taken of forcing air into it before it reaches the filters either by letting it fall down a series of small steps, passing it through perforated trays, &c. &c. The arrangements for sprinkling the effluent on to the filters are becoming more varied and more numerous every day.

In fixing the area of the filter beds it may be assumed that it requires 1 square yard or 9 square feet for every 200 gallons where the effluent is run straight through the beds and not kept in contact with the filtering material; one extra bed should always be provided, so that each filter may get periodical rests. If it is decided to adopt the contact system, it may be assumed that each filter-bed will hold liquid equivalent to 30 per cent. of its cubical contents, that is to say, if a filter-bed holds 100 cubic feet of filtering material, it will, when in full working order, be able to deal with 188 gallons of effluent at each time of filling. The English cycle for filtration by the contact system is two hours for filling, two for resting full, two for emptying, and two for aërating, or eight hours in all; each filter is thus used three times a day, so that with this cycle there must be at least three filters with one as a stand-by, or four in all. It is not at all certain whether, when great purity of the filtrate is required, it will not eventually be necessary to have multiple filtration, but in most places this will be rather a difficulty on account of the want of fall; it would, however, be quite feasible in the hills and may be found absolutely necessary, for the sewage will be strong and there will be nothing to compensate for this in the matter of high temperatures.

The final outfall or point of discharge is a matter for consideration, but does not carry with it so much importance as is the case in England. Many of the inland towns of England discharge the effluents from their so-called purification works into small brooks or streams, and some comparatively large rivers, both of which form in many cases the sources of the drinking supply for towns lower down. Only the liquid portion of the London sewage is discharged into the Thames, while the resulting sludge, containing 90 per cent. of moisture, is carried out to sea in steamers. Now in India circumstances are somewhat different, and it is as well perhaps that they are so, seeing what the strength of the sewage is. We have first of all the enormous rivers of India, containing at all times of the year vast bodies of water in motion, and always ready to quickly purify, by oxidation, any organic matter that falls upon it; then we have the rivers which only flow full during the rains, but whose sandy beds are natural filters; there are also small *nalas* or drainage channels, whose beds are so dry during the dry weather that they will readily absorb any quantity of liquid; tanks too are available as receptacles for sewage filtrates, as has been shown to be the case in the experiment herein described. These are all outfalls which are available for carrying off the liquid constituents of sewage that has been decomposed and filtered, and it remains to be seen whether the masonry drains that run at the sides of municipal streets could be utilised for carrying off not only the filtrates from the filters, but even the effluent from a septic tank before filtration, for such an effluent is probably not more impure than the other liquid contents of the drains. Then last, but not least, we have the sun and wind, which seem to have much greater purifying effects in this country than they do in colder climates, more especially when the matter to be purified is kept in motion.

If, then, we have these tremendous natural advantages in the matter of outfalls, it would seem to be superfluous to attempt to set up a chemical standard of purity for the effluents and filtrates. The Local Government Board of England have more than once been asked to lay down a standard of purity for sewage effluents, but they have refused, on the ground that all the circumstances of each case should be taken into consideration. Practically all that we require to do in this country is to dispose of our night-soil in an inoffensive and cheap manner, and no standard of chemical purity can help us when our senses of sight and smell are offended. The present tests that are employed are those that were originally devised for the analysis of water to ascertain whether it had been polluted; all of them, therefore, are most delicate tests, and quite unsuited to such a gross material as sewage, about the pollution of which there can be no question. Then, too, some of the tests are unsuited to this country; the oxygen absorbed and incubator tests may be taken as instances. These tests have to be carried on in a normal temperature of 80 deg. Fah., which was probably taken as being the summer heat in England, when putrefactive changes occur

most rapidly; in Calcutta, at any rate, the temperature for these tests ought undoubtedly to be the maximum temperature in the shade during the hot weather.

In consideration, therefore, of the very unequal results that have been obtained by the chemical analyses of samples of effluents and filtrates from this experiment, and of the evident unsuitability to this climate of the various chemical tests and methods in vogue in England, it has been decided to carry out a fresh series of tests during the cold season. In the meantime some of the leading chemical analysts in England will be consulted, and the difficulties of chemical work in this country explained to them.

Finally, can the septic tank system be worked by native agency? As long as the author was in Calcutta the experimental works were visited daily and sometimes twice a day, but owing to his other duties he frequently had to leave Calcutta on tour, and he was thus away for the whole of September and October. The working of the septic tank and filters was left, during such absences, in charge of a native overseer and two prisoners; on his return, after the long absence, at the beginning of November, the author found the work going on just as evenly and smoothly as when he was able to attend to the matter daily. The author is therefore of opinion that the septic tank system is undoubtedly a satisfactory method of disposing of sewage when a small supply of water of about half a gallon per head is available, and that probably it will be found equally satisfactory when the quantity of water per head is even less. The experience of the septic tank system of disposal in the Presidency Gaol has shown that the necessary structures may be placed in close proximity to crowded thoroughfares without causing any nuisance or offence, and that the system can be worked by native agency.

THE HOUSING OF THE POOR.

MEETINGS AND MOVEMENTS.

Movement to Abolish Slum Dwellings at York.

A LARGE number of ladies and gentlemen interested in the health and progress of York met by invitation of the Lord and Lady Mayoress (Alderman and Mrs. Purnell) at the Mansion House, and decided to form a new local society, to be know as the "York People's Homes Association." The object in view is akin to that which has for some years past prompted action on the part of other and larger towns where slum dwellings exist as a standing menace to the health of the community. The prime movers in the scheme desire to improve the sanitary conditions of the lowest quarters of the city, and bring into operation some really satisfactory system for the better housing of the poor. About 14 per cent. of the population of York are among the humblest of the small wage earners, residing mostly in the oldest, meanest, and most congested parts of the city, and the death-rate in the worst of those districts—Hungate—frequently approaches 40 per 1000 per annum. The York Corporation has not yet adopted the Housing of the Working Classes Act.

Northamptonshire County Council.

SPEAKING at a meeting of the Northamptonshire County Council on the question of reform in the law relating to insanitary dwellings and insanitary areas, the Marquis of Northampton referred to the recent speech of the Home Secretary. He said that a committee on this subject, on which he formerly worked with Mr. Ritchie, went thoroughly into the problem. The real question was practically this. Certain lands which had insanitary dwellings possessed a very high market price, and in order to acquire them the market price had to be paid. In these cases the ground landlord obtained three or four times more rent for his land than any artisans' dwellings company would be prepared to pay for it in order to erect proper dwellings for the working classes. The ground landlord was placed in the position of choosing whether he would consult the interests of himself and his successors, or whether he should give as charity his land for a certain purpose. The question would have to be settled, sooner or later, "Who is going to pay the difference between the market value of the land and the sum the land must be acquired at for working-class habitations to be built upon it at rents within the reach of the working classes?" It introduced the great question whether the State or the municipality should pay the difference, or whether the condition of affairs should go on as it at present existed.

Lecture at Tamworth.

AT a lecture given at Tamworth by Mrs. O. M. Aldridge (National Housing Reform Council), under the auspices of the Educational Committee and the Women's Guild of the Co-operative Society, Dr. H. J. Fausset presided over a large attendance. Mrs. Aldridge, who is a very fluent and ready speaker, denounced the back-to-back system of dwellings for the working classes as being the most insanitary of any class of houses. Taking the lowest possible standard, she stated that every house should contain at least three bedrooms, with a good kitchen, and a cheerful sitting-room. She advocated the erection of modern dwellings by Town Councils and co-operative societies, but pointed out the absurdity of electing upon Town Councils the owners of dilapidated cottages and other slum properties, as such men would do all they could to make the Housing of the Working Classes Act inoperative. She urged that model dwellings, when built under the Act, should remain the property of the Local Authority, and should not be sold to individuals. There was a strong current of Socialism running all through the lecture, which, however, was not devoid of humour, and was illustrated with limelight views, which revealed startling contrasts between the homes of the poor and the mansions of the nobility.

A LOCAL Government Board inquiry was held at Bournemouth last week with respect to the application to extend the Borough boundaries so as to include the parishes of Winton, Pokesdown, and Southbourne, which would more than double the existing area, and add 13,000 inhabitants to the borough. Opposition was offered by the Pokesdown and Christchurch Authorities.

BATH AS A HEALTH RESORT.—The Town Clerk of Bath writes: "The present season at Bath, far from being a bad one, or giving rise to any grumblings in this respect, promises to be one of the most successful ever experienced. The receipts at the baths for the past three-quarters of the financial year, which ends in March, exceeds by £750 those for the corresponding period of 1899, while there has been an increase in the number of baths given of nearly 7000. In 1870 the income at the baths was considerably under £2000—or, to be precise, £1854 18s. 5d. By the year 1880 they had risen to £2717, and in 1890 to £6543 17s. 10d. In the previous year they totalled as high as £7000, this rapid rise being due to the enlargement of the King's and Queen's baths, when a new wing was opened by the Duchess of Albany, in which was installed a complete and up-to-date system of continental treatment. Since that time Bath has well maintained its position, and there is every likelihood of the receipts of the present year, ending with March, constituting a record."

ARSENIC IN BEER.*

CIRCUMSTANCES WHICH LED TO THE INQUIRY.

At a meeting of the Sanitary Committee held on December 1st, 1900, I called attention to an extensive epidemic ailment attributable to the presence of arsenic in beer which had occurred chiefly in Manchester and the neighbourhood, and pointed out that there was reason to fear that this county had not escaped.

The first circumstance which excited suspicion among medical men was the occurrence, during the preceding few months, of a phenomenal increase of cases of peripheral neuritis, an affection which is usually met with among persons who are addicted to alcoholic excesses, especially spirit drinkers.

To Dr. Reynolds, Assistant Physician to the Manchester Royal Infirmary, and Visiting Physician to the Manchester Workhouse Infirmary, the credit is due of first recognising the true nature and cause of the malady. Having had occasion to treat numerous cases at both infirmaries, it became apparent to Dr. Reynolds that while most of the signs and symptoms of alcoholic neuritis were present, other symptoms presented themselves in most of the cases which were not characteristic of that disease, but which were characteristic of arsenical poisoning. He and others also observed that the large majority of the patients then suffering from peripheral neuritis were beer drinkers, and this led him to suspect beer as being the vehicle of the arsenic. His suspicions having thus been roused, Dr. Reynolds analysed certain samples of beer sold in Manchester, with the result that, on November 18th, he found a "considerable amount" of arsenic in the samples. The presence of the poison was subsequently confirmed by himself and others, and thus, through the publication of the facts in the press, on November 23rd, the scare arose which has led to this and other inquiries.

The source of the arsenic was at first a mystery, but in course of time it was conclusively traced, in the first instance by Professor Delépine, of Manchester, to the use of contaminated glucose, and as the investigations proceeded, evidence soon began to accumulate which pointed to the conclusion that one firm only were responsible for the manufacture of the arsenical glucose, a conclusion which has since been amply confirmed; I may say at once that the firm in question were Messrs. Bostock and Co., Liverpool.

In the Report of our County Analyst upon the chemical aspect of the question, which is embodied in this Report, the Committee will find a concise statement regarding the process of manufacture of glucose, which clearly explains the source of the arsenical contamination.

HOW THE INQUIRY WAS CONDUCTED.

The Committee having approved my suggestion that the matter should be specially inquired into, and having passed a resolution instructing the Inspectors under the Sale of Food and Drugs Act to curtail for a time the routine work and devote their attention to the collection of samples of beer and brewing materials to be tested for arsenic only, no time was lost in getting to work.

As time was of importance, I immediately invited the co-operation of the Medical Officers of Health of the various districts of the county, including county boroughs, to whom I addressed a circular-letter setting forth the sort of information I was desirous of obtaining, and enclosing a printed sheet of questions. The immediate object I had in view was to locate any cases which might have occurred in this county, and to ascertain, if possible, the source of the implicated beer. To have attempted to obtain this information by a direct appeal to every medical practitioner in the county would have involved considerable delay, and such an appeal, I feel satisfied, would only have met with partial success. On the other hand, previous experience having taught me that I might rely upon the willing help of local Medical Officers of Health, I did not hesitate to seek their assistance. They, of course, both from their own experience as medical practitioners and because of the facility with which they could directly ascertain the experience of their fellow practitioners, were in a position to supply the needful information with less delay and with greater fulness than would have been possible had I adopted the alternative method of a direct appeal to every medical practitioner. At the same time, I did not entirely confine my appeal for information to Medical Officers of Health, as it appeared to me that, supposing there was substantial ground for alarm, many cases would probably be met with among the large class of persons who habitually seek hospital treatment. Accordingly, I decided to communicate direct with every medical man engaged in hospital practice throughout the county.

I am pleased to state that very full information soon reached me as the result of both appeals. In the course of a few days every Medical Officer of Health, including those of county boroughs, had filled in and returned the circulars, as had also most of the medical members of the hospital staffs, and I was thus in possession of information, not only as to the localities where cases had occurred, but also, in many instances, as to the suspected sources of the arsenical beer. At first the Inspectors had no information to guide them in the collection of samples, but as the returns referred to came in, I was able to make suggestions from day to day as to how they might best direct their movements with the view of securing the fullest possible value, in the shape of pertinent information, in return for the time and labour involved in the collection of samples and in the analytical work.

EXTENT OF INJURY TO HEALTH.

It is impossible to gauge, even approximately, the amount of injury, from a health point of view, which has resulted from this wholesale poisoning by arsenic in the Midlands, but it is likely that many have suffered in a mild degree who either did not seek medical assistance or the cause of whose illness was not recognised. Again—leaving out of consideration the misery which must have resulted from thousands of people being incapacitated from work for long periods—it is not unlikely that, among those who have suffered most, organic changes may have resulted which will cause a permanent impairment of health sufficient to partially, if not entirely, prevent them from following their usual occupations, and lessen their chance of recovery in the event of serious illness in the future. In all probability, also, fatal cases have occurred which, before the true nature of the illness was discovered, were attributed to alcoholic neuritis.

Another consideration which occurs to me is, how long may not poisoning from arsenical beer have been going on, in a milder and unrecognisable form, owing to the use of less seriously contaminated glucose? Supposing that impure sulphuric acid was not used for the first time some months ago in the preparation of glucose, then it is more than likely that mild cases of poisoning did take place, and that it was only when an exceptionally contaminated acid was employed that the quantity of arsenic in the beer was sufficient to make its presence apparent in so alarming a manner.

So far as I can discover from available records, arsenical poisoning on such a scale as this has not previously occurred in England, but, in 1888, as described by Berthélemy, 405 cases of poisoning occurred at Hyères, owing to a mistake on the part of a wine merchant who poured a solution of arsenic into wine

* Abstract from Report of Dr. Geo. Reid, County Medical Officer, Staffordshire, January 16th, 1901.

casks. The symptoms as described in these cases corresponded with those observed in the beer poisoning cases, and I may here mention that it has been suggested that alcohol, being also a neurotic poison, may increase the toxic effect of arsenic.

NATURE OF ILLNESS.

At this point it may be convenient to refer, very shortly, to the nature of the illness from which the patients suffered, as the Committee will then be able to appreciate why it was so difficult to arrive at its true origin.

Whatever the explanation may be, it would appear that the cases in this county, on the whole, have not been so serious as those which have occurred in Manchester and adjoining districts, and I have no official information of any deaths having occurred, although some patients have suffered, and are still suffering severely.

For the following summary of the symptoms usually met with I am indebted to the very full descriptions of cases in articles communicated to the medical journals by medical men practising in districts where they have mostly occurred, including Staffordshire; I have also personally observed the symptoms of patients whom medical practitioners have been good enough to afford me an opportunity of examining. I merely give the prominent ordinary symptoms, and I have avoided technicalities:—The first signs and symptoms to make their appearance are usually dyspeptic troubles, headaches, and irritation of the eyes, accompanied by a puffy condition of the lids and a watery discharge. The feet are swollen and tender, and there is a feeling of burning and tingling, so much so that patients insist upon keeping them uncovered; in many cases also, apart from paralytic trouble, patients are unable to walk on account of this tenderness. In many cases there is tenderness on pressure of the calf, and in the severer cases there is paralysis, more or less complete, chiefly of the arms and legs. Various affections of the skin are met with which cause great irritation, and sometimes sores of various kinds cause considerable uneasiness, but the most characteristic skin affection is a hardened and scaly condition, especially of the hands and feet. Pigmentation or darkening of the skin is also frequently found on various parts of the body, including the face. This pigmentation, however, does not seem to have been so constantly met with in the Staffordshire cases as in those which occurred in Manchester and the neighbourhood. The circulation is feeble owing to weak action of the heart, and in some cases, although by no means in all, there is a rise of temperature.

Now, had the symptoms just enumerated been characteristic of arsenical poisoning only, the true nature of the phenomenal epidemic would not for so long have been overlooked, but, considering the fact that with the exception of the pigmentation of the skin —which is characteristic of arsenical poisoning, but which is not present in all cases, and is frequently only apparent when carefully looked for—all the symptoms are common both to the well-known ailment alcoholic peripheral neuritis and arsenical poisoning, it is by no means surprising that the true nature of the cases should have remained undiscovered for some months.

Dr. Reynolds, who, as I have already stated, was the first to throw light upon the mystery, had his suspicions aroused by observing pigmentation in several of his cases, and by noting that the cases occurred among beer drinkers and not among spirit drinkers, as is usual in the case of peripheral neuritis.

POISONOUS DOSE OF ARSENIC.

From the County Analyst's report it will be seen that the amount of arsenic, in the form of arsenious oxide, present in the beers, varied from under $\frac{1}{20}$ grain per gallon to just over $\frac{1}{2}$ grain.

Arsenic may give rise to poisonous symptoms when taken in one large dose or in continued small doses. Also, a dose which may cause symptoms of poisoning in one person may be taken with impunity by another—in fact, there are few drugs which act more diversely upon different people—and even when taken in medicinal doses, if continued for some time, arsenic not infrequently gives rise to symptoms which may become serious unless its use is discontinued.

The medicinal dose of arsenious oxide is from $\frac{1}{60}$ to $\frac{1}{12}$ grain, and, bearing in mind that some of the samples of beer contained as much as $\frac{1}{2}$ grain per gallon, it follows that a little over one pint of such beer contained the maximum medicinal dose of the drug. Probably the majority of people might take more than this amount, for a period, without injury; but in view of what I have just stated, and considering the fact that thousands of people must have been drinking arsenical beer daily, one may reasonably conclude that among these there must have been a considerable number of persons who were hypersensitive to the drug. This being the case, then, and supposing that only from one to two pints per person per day were consumed, one would not be surprised to meet with symptoms of, at least, mild arsenical poisoning. If, on the other hand, for pints we substitute quarts—which in all probability would be a truer estimate of the actual consumption among the class who have suffered—then, as the quantity of arsenic taken daily would much exceed the maximum medicinal dose, the recent calamitous experiences would at once be accounted for.

(To be continued.)

A TEST FOR EFFICIENT PASTEURISATION OF MILK.

How can it be seen or demonstrated on a sample of milk whether it has been sufficiently heated or not? This is, strangely enough, a very simple matter. In the year 1889, Professor Babcock, of Wisconsin, showed that when hydrogen peroxide was added to natural milk it was split up into water and free oxygen, while milk which had been previously boiled had no such effect. Later investigations have proved the presence in milk of an unorganised ferment, or enzyme, to which this reaction is due. This enzyme is destroyed by being heated to a temperature of 176 deg. Fah. It is found in all milk, and in the products of milk, viz., cream, separated milk, butter-milk, and whey, so long as these have not been heated to 176 deg. Fah. or over; it can even be demonstrated in butter provided this is made from cream which has not been heated to 176 deg. Fah., or over. The addition of one drop of a diluted aqueous solution of hydrogen peroxide to a spoonful of fresh milk will produce free oxygen, and the presence of this can be easily demonstrated by adding a few drops of a solution of one or other of the many chemicals which change colour perceptibly in the presence of free oxygen, preferably potassium iodide and starch or paraphenylendiamin. Two drops of an aqueous solution of the last-named reagent produce, in this way, a dark indigo-blue colour in milk when it has not been heated above 176 deg. Fah. If the milk has been previously heated, no change of colour takes place when one drop of hydrogen peroxide and two drops of paraphenylendiamin are added. Supplied with a small bottle of each of these reagents and a small test-tube, all of which can be had for a few pence, anybody can in a few minutes tell whether milk has been heated to the named temperature or not.

A HOSPITAL for infectious cases is to be erected jointly by the Rochford Rural District Council and the Shoeburyness Urban District Council.

CORRESPONDENCE.

(We do not in any way hold ourselves responsible for opinions expressed by our correspondents.)

(To the Editor of THE SANITARY RECORD.)

THE ARTIFICIAL COLOURS IN SWEETS.

SIR,—One cannot, after receiving and examining a great number of sweets, help being struck with the abnormal and artificial stage at which the manufacture has now arrived.

If the embellishment of our babies' bellies, or the ornamentation of the stomachs of adults with gorgeous colours was the *summum bonum* of confectionery, one could better understand the state of affairs now reached.

The good old-fashioned wholesome toffey-candy, hard-bake—bulls' eyes—liquorice barly sugar, and so forth, are placed upon a back shelf, and mixtures of goodness knows what are adorned with tints of the rainbow, and placed in a conspicuous position in every sweet shop.

Possibly this has been going on so long that neither the manufacturers nor the vendors can help themselves, and the cry is, "We cannot sell our goods if not bright and attractive to the eye."

If that is so it is time that the Sale of Food and Drugs Acts should be put into operation to suppress any and all forms of artificial colouring in foodstuffs.

ARTHUR ANGELL,
January 17th. *Public Analyst.*

A CLEAN BILL OF HEALTH.

SIR,—I am obliged to Mr. Irwin for the information he gives concerning Ramsey, in answer to my letter in your issue of the 10th inst., about Penmaenmawr, and I am sure that he and those associated with him in the betterment of that pretty watering place deserve well for the improved sanitary conditions which there obtain.

It would, however, appear that Mr. Irwin did not carefully read my letter before writing his reply. The total absence of zymotic mortality in one year, *i.e.*, from January to December inclusive, the period covered by annual health reports, and immunity from any infectious sickness in the next, in the same urban district, is the rare circumstance recorded of Penmaenmawr, not its freedom from infection between any two dates. If I had wished to convey this I would have stated that the district has been wholly free from infectious disease from August 27th, 1899, to the present time, almost 17 months; and it continues so—a better record still. The coincident case, which interrupted a previous period of freedom, was a mild imported "suspected" one, but as it was notified it was accepted as such.

It is an axiom in district hygiene, as in other departments of public work, that it is easier to make bad good than good better, in practice largely because of the anomaly that the more successful sanitary measures are the less apparent becomes the need for them. The conditions of Penmaenmawr as a health resort have always been good, but they would now seem to be better; and negative quantities will apparently be required wherewith to compute further improvement! The mutual relationship of cause and affect appears to have had singularly speedy confirmation in the fact that the past two years have witnessed the completion here of comprehensive works of water supply and drainage, the institution of a regular system of scavenging, and the erection of a large number of well-equipped houses for the industrial population.

Information as to similar conditions elsewhere, if such exist, will yet be welcome.—Yours faithfully,

Penmaenmawr, ERNEST WORRALL.
January 19th.

THE CUP OF THE SACRAMENT.

SIR,—From time to time letters have appeared in sanitary journals relative to the present method of administering wine to the people in the ceremony of the observance of the Supper of our Lord. The danger of the present system of so doing has not, however, been sufficiently emphasised.

For the last sixty years sanitarians have laboured energetically, and with beneficial results, to instil into the lay mind some thought as to the means by which it may in the ordinary daily round protect the body from the many snares which lie in wait for it, and which are too often successful in obtaining hold upon the careless, and often with disastrous and fatal effect. These efforts have been primarily in connection with our domestic sanitary arrangements, and secondarily with the many opportunities of reducing risk to health in our every-day life in the world.

The subject under review is obviously in the second class of these great measures of sanitary reform. That the efforts of sanitarians have been successful is conclusively proved by the great decrease in the percentage of preventable diseases, and this success is greater than would appear at first sight when we take into consideration the increase of population in our large towns, with the consequent necessary restricted area for habitations—a condition of things which would be absolutely impossible were it not for the very laudable improvements in our sanitary arrangements and in the conduct of the details of our daily life, due entirely to those once-despised sanitarians, who are, I fear, not appeciated in some quarters even now at their full worth.

Now, these same sanitarians, not content with invading the domestic hearth, nor with penetrating into the inmost recesses of the factory and the workshop, and saying, "This thing must not be," or "That practice must cease," as occasion may demand—not content with purifying rivers and improving hospitals and kindred works, are now bold enough to attack the Church, and that in one of its most sacred services—the holy Sacrament.

Our clerical friends will doubtless be astounded at such audacity, and object to any attempt to dictate to them about the management of the details of their services, and I may say at once that from a sentimental point of view I quite admit that the system I am advocating has its drawbacks, but at the same time we cannot conscientiously allow sentiment to hinder sanitary reform.

Undoubtedly—and I say it with all emphasis—the present custom of numerous people of different ranks, habits, and habitations, drinking out of one cup is most dangerous and therefore most reprehensible, and it should be stopped with the least possible delay.

I admit that this will not be accomplished without much difficulty, as not only our clerical friends, but the majority of the worshippers in our churches, are so attached—and, with the exception of the practice under discussion very rightly so — to every detail of the services, that we may expect to hear many bitter attacks upon our latest contention; and it will probably be years before our efforts meet with success and one more sanitary reform has triumphed.

We shall be told that our Lord will surely protect His children in the act of worship, and that notwithstanding the nineteen hundred years that have passed since the institution of the Sacrament, the ceremony should still be carried out exactly in the same way now as then. I anticipate this argument, and we would point out that it will not endure any consideration; years alter our habits naturally and necessarily, and what was done nineteen hundred years ago is not done now.

If the Lord's people are to be specially protected in His church, why not in their own houses—why not in

the streets? In short, why trouble about sanitation? It would not appear to be necessary. I may mention that the clergy themselves have conduced to this appeal. They are provided with a chalice napkin for the purpose of wiping the cup after each user, but very few avail themselves of this, and the omission has been severely commented on by many.

I call upon all sanitarians, and in fact on everybody with common sense, to decline to encourage this careless infringement of ordinary precaution by insisting upon small cups being provided in the churches they are connected with.

This system would in no way detract from the solemnity of the service, and would be one more point gained in the direction of sanitary reform.

In conclusion, I may mention that I have already been met by the argument that in some churches hundreds of cups would be needed. That such an argument can be raised is to accentuate the urgent necessity of immediate alteration in the present system. — Yours faithfully, WALTER MARKHAM.

79, Essex-road, N.

TUBERCULOUS DISEASE OF COWS.

SIR,—I should feel obliged to any of your readers who can give me information on the following points. By an order of the Local Government Board of March 11th, 1899, it is directed that "such disease *of the udder* as shall be certified by a veterinary surgeon to be tuberculous" shall be deemed to justify the stoppage of sale of milk, &c. (I need not quote more fully).

I should be glad to know whether, and under what statute or order, a district Council have power to cause the application of the tuberculin test, in such manner, and with such safeguards as to eliminate the many known causes of possible error attendant on the use of this test, or to cause it to be used at all.

Whether I am right in supposing that the tuberculin test properly applied will show whether or no the cow is suffering from tuberculosis, but will not indicate the organ or organs affected.

Whether there exist any other means whereby a veterinary surgeon can ascertain with certainty the presence or absence of tuberculosis, slight or severe, in the udder of a cow; and what guarantee has the Council employing him that he may not fail to detect the disease in some or many cases.

Assuming that there may be some cases that could be certainly detected without the use of tuberculin, what would be the percentage of such cases likely to be so detected in ordinary cows on a farm passing most of their time turned out to graze?

What would be the position of the District Council as to liability to damages in cases where the veterinary surgeon might from imperfect knowledge of the law exceed his legal powers, or through avoidable causes (as error of diagnosis), inflict loss or injury on the cow-keeper. QUI HI,

Member Sanitary Institute.

January 21st, 1901.

LAW CASES.

Infringement of Infectious Diseases Notification Act.

AT Chester-le-Street, Dr. J. A. Irvine, Fatfield, was charged at the instance of the Rural District Council with offences under the Infectious Diseases Notification Act, on October 20th and 22nd, and on November 5th. Mr. H. E. Ferens (Durham), who prosecuted, said Dr. Taylor, the Medical Officer of Health of the Chester-le-Street Rural District Council, discovered that in the months of October, November, and December there were several cases of scarlatina in the district which had not been notified, as required by law. All of them were under the medical attention of Dr. Irvine, whose duty it was to notify the Medical Officer of Health of the existence of the cases. Mrs. Mary Jane Bell, Post-office-row, Fatfield, said her daughter Grace died on October 24th. She was taken ill on October 15th, and attended by Dr. Irvine. He said she was suffering from scarlatina, and he would have to report it. Barbara Robson, Fatfield, said her granddaughter was taken ill in November, and witness sent for Dr. Irvine. He came and said it was a case of scarlatina.

After other evidence, the Bench fined the defendant 20s., and costs in each case, the costs to include witnesses' costs.

Removal of a Fever Patient.

AT Lanchester, Robert McDonald, miner, of Quebec, was summoned under the Public Health Act for obstructing a magistrates' order for the removal of his child to the Infectious Diseases Hospital at Langley Park.

Mr. W. LISLE, who prosecuted on behalf of the Lanchester Rural District Council, stated that the defendant's boy, who was suffering from scarlet fever, was ordered to be removed to the hospital, there not being sufficient accommodation in McDonald's dwelling to isolate the patient. Sergeant Gillespie, along with Mr. Halkier, the superintendent of the hospital, went to the defendant's house with the ambulance van to remove the lad, but McDonald declined to allow the child to be taken away. The child was still lying in the same room, and was recovering from the disease.

Mr. CORKE (from the office of Mr. Edward Clarke, Newcastle) defended, and pleaded guilty. What he complained of was that the order was obtained on *ex parte* statements. He contended that there was ample accommodation for the isolation and nursing of the patient. Defendant had done all he possibly could to prevent the disease spreading, and had even stopped off work from the pit.

The magistrates said though, as the law stood, they were obliged to convict. They quite agreed that it was very hard for the defendant to be precluded from obtaining a hearing on the question of accommodation at the local law courts if he had a good defence. His only remedy, if an order were obtained on an *ex parte* application was obstruction and appeal to the Court of Queen's Bench. They must convict, and they fined the defendant 5s. and costs.

A LOCAL Government Board inquiry was held recently into the application of the Manchester Corporation to borrow £12,500 for laying out Brookdale Estate, Newton Heath. The estate was recently purchased by sanction of the Local Government Board for £26,500.

THE Local Government Board has decided on despatching a Medical Inspector to the several Irish boroughs and having reports from the Inspectors as to the working of the Sanitary Act in the principal Irish cities. These reports will be subsequently printed and issued in Blue-book form, following the procedure in England. Last week Sir J. Atcheson M'Cullogh, Local Government Board Medical Inspector, arrived in Limerick, and was engaged in a private sanitary inspection of the borough. By a curious coincidence it was stated at the Corporation meeting that though the outlay on the cleansing of Limerick was £8000 a year, or one-half the total city revenue, the streets and thoroughfares were in a most unsanitary condition. No meeting of the Cleansing Committee had been held for weeks.

OBITUARY.

DR. A. N. COOKSON, NUNEATON.

At Nuneaton on Sunday night, the 6th inst., the death occurred of Dr. A. N. Cookson, the oldest medical practitioner in that town, and brother of Dr. Samuel Cookson, of Stafford. He had for some time been in failing health. He settled at Nuneaton many years ago, enjoyed a large practice, and held the appointments of Medical Officer and Public Vaccinator of the Nuneaton Rural District. Dr. Cookson leaves a widow and one son.

DR. SEDGWICK SAUNDERS.

It is with sincere regret that we have to announce the death from inflammation of the lungs of Dr. Sedgwick Saunders, Medical Officer of Health and Public Analyst to the Corporation of London. Dr. Saunders was born in the year 1824 at Compton Giffard, near Tavistock, Devon, where his ancestors had resided for many centuries. He was educated at King's College, London, and at the age of nineteen commenced his medical career as a student at St. Thomas's Hospital. St. Thomas's, it may be mentioned, is one of the Royal hospitals over which the Corporation exercises jurisdiction. Consequently it may be said that his association with the City commenced even at that early period of his career. His hospital course was a notable one, and when he left to commence practice in the year 1846 he carried with him many of the principal prizes of the medical school. Preferring an adventurous career to what he considered the humdrum life of a private practitioner, the Doctor entered the army as an assistant surgeon, being gazetted to the Royal Fusiliers, with whom he served in the West Indies and North America. Returning four years later to England, he was placed on the staff, receiving an appointment as Medical Officer at the Military Prison, Fort Clarence, Rochester. In 1851 he was ordered to the seat of the Kaffir war, sailing in the ill-fated Birkenhead in January of the following year. What at the time seemed to be a great misfortune proved, as a matter of fact, the saving of his life. When a few days out he was seized with illness, the symptoms proving so serious that it was necessary to land him at the first calling station. The boat, it will be remembered, subsequently sank in St. Simon's Bay, and all hands on board were lost.

Upon recovery from his illness, the Doctor resigned his commission, and commenced a private practice in the City of London. From the first he took an active interest in the local affairs of the one square mile, serving an apprenticeship first of all in connection with parochial life, and afterwards being elected as one of the representatives of the ward of Cordwainer in the Court of Common Council.

The year 1874 brought the Doctor's career as a Corporator to a close. Dr. Letheby, who had succeeded Sir John Simon—who may be looked upon as the pioneer of the developments in the direction of sanitary science that have been witnessed during the past century—resigned the position of Medical Officer of Health and Public Analyst after a lengthy service. Dr. Sedgwick Saunders became a candidate for the position. Some little controversy arose as to whether he could retire from the Court, and be elected to the post he sought. Legal opinion was obtained, and, on the authority of the Recorder, the candidature of the Doctor was allowed to stand. The appointment was subsequently made at the meeting of the Commissioners of Sewers. Immediately afterwards the appointment of Food Analyst was made, four candidates presenting themselves, and the Doctor obtaining the appointment by a majority of 34 over Dr. Tidy, who was supported by 15 votes. From that time until the breakdown of his health last year the Doctor was not only one of the ablest, but one of the most loyal officers connected with the Corporation. "To him," says the *City Press*, "we owe in a great measure the improvement that has taken place in the sanitary condition of the City in the past quarter of a century, while to the energy he displayed in training the members of his staff, and personally superintending their work, we are indebted for the immunity from disease and the low death-rate that have been characteristic of the City for a long while past." Apart from the annual report he presented—which in itself was a masterly review of the work of the year, and an outspoken retrospect of events of importance from a sanitary point of view—the Doctor had published many notable works on medical topics, several being to this day regarded as classics in the profession.

By his death the City loses one of its most distinguished officers, the medical profession a man of mark, and his large circle of friends an associate whose memory will long be held in affectionate regard.

National Health Society.

OFFICIAL TRANSACTIONS.

Training Course for the Certificate of the Sanitary Inspector's Examination Board.—Attention is specially drawn to the fact that Training Lectures in preparation for this examination commence next week, on Tuesday, the 29th inst., and intending students should loose no time in communicating with the Secretary, 53, Berners-street. Lectures on "Nursing" begin on January 24th, and a course on "First Aid" on January 28th. Details of these syllabuses will appear next week in this column.

An interesting paper, entitled, "Is the High Infantile Death-rate Due to the Occupation of Married Women?" appears in the January number of the *Englishwoman's Review*, by Mrs. Greenwood.

ASSOCIATION OF NATIONAL HEALTH WORKERS.

The second "At Home" of the Association of National Health Workers will be on the last Saturday in January, the 26th inst., at 3 p.m., at 53, Berners-street. Mr. Westaway has been asked to preside.

Messrs. Campion and Jeune, the examiners of Private Bills, sat in Committee Rooms 16 and 17 of the House of Commons, to receive proof of compliance with the Standing Orders of Parliament in respect of the measures deposited for consideration in the ensuing session. There was no opposition in the case of the Brighton Corporation Bill, the City of London (Spitalfields Market) Bill, the City and South London Railway Bill, and the Islington and Euston Railway Bill, and, the formal proofs required by the Standing Orders having been given, the examiners declared that the regulations had been duly complied with. The measures will accordingly be reported for first reading. In the case of the Kingston-upon-Thames Corporation Bill, the measure was marked in the examiners' list as "dead." The reason for this is that the burgesses of the borough have recently been polled on the matter, and have rejected by a large majority the Corporation's proposal to construct municipal tramways for the district.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

"THE QUEEN IS DEAD."

NOTHING within the memory of living man has sent such a thrill through the wide world as the news which flashed along the telegraph wires on Tuesday last:—"The Queen is dead." So the word was passed from man to man, and none but realised that a great and terrible blow had befallen our Empire. Under the shadow of so great a sorrow it is impossible to write as we may be able to in future days, for our noble Queen has been so inseparably linked with our national life for so long a period that we cannot realise that she has passed away and is no more.

Who can ever measure what her wise and beneficent rule has been to the British Empire? Under her the English-speaking race has taken foremost rank in the nationalities of the world. And this not so much by the triumph of arms, as by the loftier ideals given to its life by the noble example of its Monarch. From the very outset of the Queen's occupancy of the throne she has done all in her power to encourage the arts of peace. Everything that would better the condition of her subjects, any plan for the alleviation of suffering or combating disease, found in her a sympathetic friend. As she spared not herself in the service of her people, so she also taught her children that their duty was to be found in works of love and service to the nation. Hence, since the time when the great sorrow came to her forty years ago in the loss of the Prince Consort, her work has been largely delegated to them, but we may be sure that she never faltered in the interest so early manifested in the social regeneration of her people. Whilst continental monarchs and their families often confine their public acts to mere military display, the members of our Royal household have ever taken the greatest delight in showing approval of works of usefulness and improvement, and in going quietly in and out among the people, to show that they sympathised with them in all attempts after happier conditions of life and service. It was this *sympathy* which bound the Queen to the people, and which was never more shown than when she came to London last spring, or in her visit to the Emerald Isle but a few months since. The plaudits then given were not the begrudged applause to a despot, but the heart echoes which ever respond to the sympathetic advances of a true and devoted friend.

As a nation we mourn the loss of our beloved Queen, but we shall ever glory in her life. It marks the emancipation of the people from political serfdom; it marks the greatest advances ever made in science, mechanics, and social reform; it marks the purification of the life of the Court, with its reflex effect upon the life of the nation; it marks the breaking down of class barriers of former days, and in many ways the advent of a practical exemplification of the brotherhood of man. For the sixty-three years of her reign, Victoria the Good strove to promote these objects, and right well did she succeed. Full of years and honours, she has passed away, but her influence will remain, and the good works she inaugurated, or saw commenced, will bear abundant fruit in the ages yet to come.

Housing at Birkenhead.

There was some straight talking at the inquiry held last week by Mr. R. H. Bicknell, on behalf of the Local Government Board, into the application of the Birkenhead Town Council for a loan to build under the Housing of the Working Classes Act, 1890. It would appear that the people to be provided for are among the very poorest in the district, and while the Council is prepared to build good sanitary houses, there is a strong feeling against building "palaces," for such was the description applied to the places prescribed by the bye-laws of the Local Government Board. That the property to be displaced was insanitary there could not be two opinions. The Medical Officer of Health pointed out that the average death-rate in the whole area embraced in the scheme was 55·8 per 1000 against 18·9 for the whole borough. Following up this evidence, and that of the Engineer and the Chief Inspector of Nuisances, came the ultimatum from the Town Clerk on the point we have mentioned. At a former inquiry the Local Government Board had insisted on the Corporation building houses at a cost of £400 each, which it was impossible to let at 5s. or 6s. per week. If the same restrictions were again to be imposed, "the Corporation would not do anything except under compulsion." The Town Clerk said he wished to emphasise this view, and believed the whole country was with them. He was quite "sure the Act would be better carried out and better understood if the Board would not insist upon houses being built altogether unsuitable for the class of tenants displaced." Of course, the Inspector could only undertake to present this view to the Board, and we hope it will receive very careful attention. It is little short of madness to take certain people from the slums and place them in dwellings with "every modern improvement." They are not capable of bearing such a change. First teach them cleanliness by putting them in places with the minimum of material capable of destruction. They must be watched like children, and compelled to comply with the elementary laws of health. When they do this, and have learnt the benefits of healthy surroundings by experience, then, and only then, they may be fitted for the better class of house.

A Neglected Health Resort.

At this season of the year many Britishers hurry off to the Continent to seek refuge from the fogs and variations of climate. Sometimes they succeed, but not always. And, after all, is the Continent, with its round of gaities and gambling saloons, the best place to seek recuperation? This question is asked by Dr. J. Oldershaw, in a letter to one of the Liverpool papers, in which he directs attention to one of our possessions, as providing a health resort quite equal to those regarded as fashionable, without their attendant evils. There is no model climate, he asserts, no country can boast of being perfect; change from one climate to another is one of the means by which invalids may regain health, and that which possesses the greatest advantages and the fewest drawbacks is to be commended. To the man of leisure in search of a mild dry climate with a moderate temperature Jamaica should be recommended. It involves only a short sea passage of twelve days in a well-appointed mail steamer, with a fair weather voyage, for at this time of the year every hour from England to the south-west brings you nearer to the soft breezes and blue sea of the Ladies' Gulf. "Kingstown," Dr. Oldershaw goes on to say, "the capital of the island of Jamaica, is a healthy city, of some 55,000 inhabitants. The soil is of a gravel bed, with a slope to the sea of 1 in 85. There is no malaria, and Kingstown is one of the healthiest seaport towns in the West Indies. A trip by the Imperial Direct West Indian Mail Service from Bristol provides at once one of the most beneficial changes of climate. A short sojourn in the island cannot but be of the greatest interest to the traveller, merchant, or brain-fagged professional, while the railway, tramcars, and well-appointed hotels assure the invalid of every home comfort, intensified by the boundless hospitality of the West Indian. To the sufferer from asthma, bronchitis, gout, rheumatism, or atonia dyspepsia, no better route could be recommended, while the botanist, horticulturist, and political economist will find in the island a wealth of natural enjoyment undreamed of. The ordinary tourist, surfeited with the joys of European spas or Norwegian fiords, will find a perfect change in the glorious scenery of this beautiful land of mountain and river."

Inoculation with Infected Serum.

According to the correspondent of the *Morning Post* at Rome, a serious scare has been caused in Italy by the death from lockjaw of a number of persons who had been inoculated with anti-diphtheria serum prepared by the Milan Serum Institute. About a month ago more than three hundred tubes of new serum were distributed to doctors and chemists in various parts of Italy, but nothing happened to cast suspicion on the purity of the serum until a number of persons who had been inoculated for diphtheria at Valdobbiadene died of lockjaw. While inquiry was being made into the causes of these deaths other cases of lockjaw following on inoculation for diphtheria were reported from other parts of Italy. It was then found that the serum used for all these inoculations belonged to the batch of three hundred tubes despatched from Milan about a month ago. Urgent telegrams were at once sent to all purchasers of those particular tubes, and two hundred and thirty of them have now been sent back to the Milan Institute. A dozen more have been traced, but the rest are either used up or untraceable. In explanation of this unhappy incident, the theory put forward is that tetanus microbes, which abound on the skin of horses and in stables, fell into the vessel used to catch the blood of horses

from which the serum was made. The greatest precautions had been taken to prevent the presence of diphtheria bacilli in the receptacle, but it does not seem that the same precautions were used with regard to tetanus. Yet if this is the real explanation it is strange that a case of lockjaw arising from use of the serum has never before occurred, since the Milan Institute has distributed quantities of anti-diphtheria serum in the past made in precisely the same manner. Last year the serum proved efficacious in checking an epidemic of diphtheria in the Venetian Provinces. The medical world and the general public are awaiting with intense interest the report of the expert commission of inquiry which has been appointed to examine the infected serum. The occurrence, however, is greatly to be deplored. Nothing is more calculated to shake public confidence in new discoveries than want of proper care in their preparation. And, further, people are hardly likely to accept as a remedy for one disease that which may contain elements of another, and that a more surely fatal one.

The L.C.C. Housing Managership.

Much interest surrounds the appointment of the head of the new housing department of the London County Council. The position, as we indicated at the time when it was resolved to create it, is somewhat novel, and upon its success or otherwise will depend similar appointments by the larger cities and towns in the United Kingdom. Several names of likely men have been mentioned, but one of the most suitable that we have heard is that of Mr. Peter Fyfe, the present chief Sanitary Inspector of the City of Glasgow. His experience is quite unique, and since he was appointed to his present position some very practical work has been done in the way of improving the housing accommodation of the poor of Glasgow. Mr. Fyfe is well known to our readers, and some of his addresses and papers are among the most valued contributions on the social problems of our day. He is by no means a man of one idea, and should he be the successful candidate, there are many matters upon which his advice might well be sought by the governing body of the metropolitan county.

The Value of School Closing.

There can be little doubt that the first step necessary on the outbreak of any infectious disease is to place a most careful watch over the elementary schools. If this is done an epidemic may be prevented, or, at any rate, its ravages restricted. This has been done in Leicester, and what in December threatened to be a serious outbreak of diphtheria is nearly stamped out. In the second week of last month forty cases were notified, but with the closing of the schools the number has gradually decreased, until in the second week of January there were only fourteen. Of course it may be that the disease has spent itself, but the Sanitary Committee of the Borough has, we think, justified its action in insisting on the closing of the schools. All parents are not careful, and nothing is thought of keeping children at school long after they have developed symptoms of a serious character. It is this lack of care that makes the appointment of a Medical Officer for every school a necessity. Children displaying the slighest indication of "sore throat" should be at once suspended from school attendance; this would stop much zymotic disease. It is better that one child should lose a few days' schooling than for hundreds of lives to be jeopardised.

Plague and Small-pox in the Country.

The country is once more disquieted by the news that plague has made its appearance on our shores. The Local Government Board have notified its appearance at Hull on the 15th inst. The steamer Friary from Alexandria, after calling at Algiers, arrived at Hull on the 10th inst. The body of a seaman, who had died before the ship's arrival, was, after the usual inspection by the Port Medical Officer of Health, removed to the mortuary, but there was then no actual sickness on board. A couple of days later, however, two other members of the crew sickened, and two more a few days after. All four died, and though the cases had at first been diagnosed as influenza, with lung complications, a bacteriological examination of the viscera made by Dr. Klein established that the cause of death was pneumonic plague. Besides the fatal cases, four other seamen were taken to hospital and isolated. They are stated to be making good progress towards recovery. The Hull Authorities are fully on the alert, and are exercising every precaution. The bodies of two of the seamen were cremated in the new Municipal Crematorium. Dr. Mason, Medical Officer of the Hull and Goole Port Sanitary Authority, is confident that owing to the prompt isolation of the disease, little danger need be apprehended by the public. Small-pox is, however, raising its ugly head in more than one part of the country to a degree that is well fitted to excite apprehension. There are a number of cases at present in Bradford, and single cases have also appeared in several other towns in the West Riding of Yorkshire. There does not appear to be any visible connection between these cases, and with regard to the outbreak in Bradford, the Medical Officer is at a loss to account for its origin. It has been suggested that it may be traced to some soldiers who returned from South Africa last October, the Bradford Authorities having been notified at the time that small-pox had occurred on board the transport during the voyage; but the connection with the present outbreak has not been satisfactorily established. A much more serious outbreak is engaging the attention of the Authorities in Glasgow. Last week Dr. Chalmers, the Medical Officer, stated in his weekly return that no fewer than 78 cases had been admitted to the small-pox wards during the week, the total number then under treatment being 121, as compared with 66 the preceding Fri-

day. The cases had for the most part been confined to the east end of the city. From Glasgow it has spread northwards to Morayshire, cases having occurred in Elgin and in Burghead, which were distinctly traceable to the visit of a sailor from Glasgow to his relatives there, he himself having been seized with small-pox on his return south. In connection with the Glasgow outbreak Dr. Chalmers mentions that the most discouraging feature is the indifference of the public to mild forms of the disease, which seriously handicaps the efforts of the Sanitary Authority. An offer by the Corporation of free vaccination had met with a most disappointing response, only nineteen persons having taken advantage of the offer. In such cases, unless the public are willing to co-operate with the Sanitary Authorities, the efforts of the latter must be deprived of much of their efficiency.

L.C.C. Rival Policies.

In view of the approaching election for the London County Council on March 2nd, a lengthy manifesto has been issued by the Conservative section of the Council, in which not only is their opponents' policy fully criticised, but their own policy is set forth in detail. Unfortunately the County Council has acquired a political complexion which it will not be easy to get rid of—if, indeed, there is any honest desire on the part of members to purge the Council of it. The Moderates in their manifesto attribute this political character entirely to the action of their rivals, and claim that "Business, not politics," is to be their watchword. The value of such a claim cannot be judged of until we have had an opportunity of seeing how the Moderates would act if they were returned with a majority. But it must at least be admitted that in some parts of their programme they proclaim a sound and much needed policy. They propose to devote particular attention to the Housing of the Working Classes—a feature of the Council's work in regard to which they have a heavy indictment for the results of the policy of the past few years—deriving wisdom, no doubt, from the experience. If they can work up the practice of the Council to the ideal they set before them, a new era in the development of the housing problem is in store for us; one in which those dispossessed by clearance schemes will first be accommodated elsewhere, and so far as possible in the neighbourhood of their occupations; in which such economy in building and in management will be observed that the rents of the new houses will be brought within reach of the poorest classes, the classes, in other words, who are the subjects of the improvements and who are dispossessed; in which building schemes will involve no charge on the rates, and co-operation with other bodies having similar aims will be sought. In other departments of the programme, such as the subject of the London water supply, there is considerable vagueness, the responsibility for action in the case we have instanced being practically delegated to the Imperial Government. It would be well if the electors would in this most important coming election adopt the advice inculcated by Lord Rosebery with so much force in connection with the Borough Council Elections, to eschew party politics altogether, and to see that none but the best men, independent of their politics, are elected to the Council Board.

The Growth of Cremation.

The report of the Scottish Burial Reform and Cremation Society, Limited, which has just been issued, besides giving a *résumé* of the operations of the society for the past twelve months, contains some instructive particulars regarding the progress of modern cremation during the last quarter of a century. The progress made, during recent years especially, has been very striking. The subject was first raised by Sir Henry Thompson in 1874; but for ten years the Government declined to sanction any cremations. In 1884 cremation was announced to be not illegal, and in 1885 was commenced in England, but still did not obtain Government sanction. Now, in 1901, not only has all Government opposition disappeared, but an Act has been passed granting to Local Authorities in England power to expend public money in erecting crematoria. The society is taking steps to have the operation of this Act extended to Scotland. The opening of the first municipal crematorium at Hull is but the commencement of a new chapter in municipal activity, and one the value of which it is impossible to over-estimate. The example of Hull is a fitting inauguration of the new century, and it is a safe prediction that the close of the century will see a complete and radical change in our burial customs, much to the advantage of the public health. Indeed, so rapid has the growth of enlightened public sentiment been on this question, that the next ten years may be expected to witness a very great reform. The report points out that many cases have been known to occur where persons who during life favoured the idea of cremation, and expressed a desire to be cremated on death, have been buried in the ordinary way; this disregard of the wishes of the deceased having been exemplified recently in the cases of two very prominent Scottish noblemen. To obviate this as far as possible it is recommended that the form of request issued by the society be signed in duplicate. Reference is also made to the fact that, during the recent outbreak of plague in Glasgow, the bodies of those who died of plague were not cremated, notwithstanding the express desire of the Health Authority—mainly owing, it is believed, to the opposition of the Roman Catholic clergy.

A Local Government Board inquiry has been held at Wakefield as to the proposal of the Corporation to purchase and close fifteen houses in different parts of the city, and to erect artisans' dwellings on a piece of land near the sewage and electric works. The property to be acquired is for street improvements in Drury-lane, Marygate, and Warrengate.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

It is be observed, with a sense of disappointment, that the scheme, originated nearly two years ago, for establishing an Orphan Fund under the *ægis* of the Incorporated Association of Municipal and County Engineers, hangs fire badly. Seeing that its purpose for providing means whereby board and education for the children of municipal engineers who have died and left them unprovided for is essentially a benevolent and brotherly one, it is the more to be regretted that a fraternal interest is not taken in it. The hon. secretary and treasurer—Mr. O. Claude Robson, late president of the association, and Engineer to the Urban District Council, Willesden—has within the past fortnight issued a circular to the members appealing for better support, and I earnestly recommend its claims to my readers.

It is not creditable that out of a membership of 950 only 66 members of the association figure as donors or subscribers, and that the total amount subscribed—which includes 100 guineas from Mr. "Johnny" Parker, of Nottingham, and three other donations of ten guineas each which do not come from members of the association—only amounts to £315. The claims of the children who are left fatherless should evoke more goodness of heart than is displayed by the list of subscribers which Mr. Robson has issued, and it is not suggesting too much to say that every member of the association can and should afford not less than 5s. per annum to the fund. If this small amount were forthcoming generally it would mean a yearly addition of £220 per annum to the fund and would enable the trustees to minister to the appeals for assistance which are made to them.

The annual volume of "Proceedings" of the Incorporated Association of Municipal and County Engineers for the year 1899-1900 has just been published. Its appearance is somewhat belated, seeing that the year ended in July last, but this I am told is characteristic of the comatose condition of the association—or more probably the Council elected by it. The volume is the smallest in bulk which has been issued for a considerable number of years, only four meetings being held during the twelve months covered by it—a truly disappointing record. The various papers read by the members are, as usual, of great value and interest, and it is to the loss of the association generally that there are not more of them. It has been suggested to me that the balance-sheet of the receipts and expenditure deserves the careful scrutiny of members, as starting with a balance of £209, this was reduced, owing to financial mismanagement, down to £87, notwithstanding that the receipts amounted to over £1000. Out of this amount the sum of nearly £440 has been spent in printing—a sum which I am assured is unreasonable and excessive. If the association is ever to become a power it is essential that it should husband its resources and establish a fund which will enable it to have its own offices and establish a library in a permanent and creditable form. On the present policy the small reserve fund of the association is in danger of being entirely whittled away.

One of the most sensibly-written *brochures* on the cause of smoky chimneys which I remember to have seen is that which has just been issued by the widely-known firm of Messrs. Joseph Place and Sons, Limited, Darwen, Lancs, entitled "Smoky Chimneys: Some Hints as to their Cause and Cure," at the nominal price of 1d. The little book is not prepared for the sole purpose of "puffing" any patent chimney cure, but gives in a concise form the "boiled down" experiences of upwards of twenty years' study and experiment, and is worth the very careful perusal of every municipal engineer and architect, who will find in it much that he can profit by.

I predicted a month ago in this column a general fall in the price of iron and building materials. That the inflated prices which have been ruling for the past two years could be long maintained was impossible, and when I last wrote to warn my readers to avoid entering into long contracts, I did so with a knowledge which was not general. That my prediction was absolutely correct is confirmed by the recent great reduction in the price of iron and coal. At the last quarterly meeting of the Midland iron trade the price of Staffordshire bar iron fell to £7 10s., or nearly £3 lower than at the previous meeting, whilst coal for manufacturing purposes has recently dropped 3s. per ton. Inasmuch as the price of all building material is regulated by the prices of coal and iron, it will be seen that the market is well on the down grade.

There is still another competitor against the electric light for public and private installations to be recorded. This is the Kitson system of incandescent lighting by pretroleum, whose offices are at 1, Victoria Embankment, Blackfriars, London, E.C. This system originated in America, and is now considerably used in New York, Philadelphia, Boston, Baltimore, &c. The company allege that their system has in numerous instances displaced the electric light and high-pressure gas burners, and claim that it is "not only the most brilliant, but the cheapest light that has ever been produced." Each lamp carries its own oil and vaporises it, thus converting it into oil-gas, which is burned in a refractory mantle, it is stated, "in sun-like incandescence." The oil used is specially prepared and refined, and termed "Kitson Incandescent Oil." The system has been adopted on a number of railways, manufacturers' premises, and for street lighting in various towns in England. Whether all that is claimed for it can be substantiated I am as yet unable to determine, but some of my readers may find it deserving of a trial.

Senex.

REVIEWS.

Arsenical Poisoning in Beer Drinkers. By T. N. Kelynack, M.D., and William Kirkby, F.L.S. Demy 8vo., 137 pages and 16 illustrations. London: Ballière, Tindall, and Cox. 1901. 3s. 6d. net.

The authors are to be congratulated on the rapidity with which they have produced this opportune book. That it should show no more evidence of haste is surprising and creditable. The earliest cases of this epidemic have been traced to the spring of 1900, but it is probable that arsenical beer has been in use for a much longer period. In fact, the outbreak has led to a reconsideration of the question of the long-known "alcoholic neuritis," and to a suggestion that this disease may, in former times, have been due to, or at least intensified by, the unsuspected presence of arsenic (page 77), which many authors have shown to be one of the most widely distributed of substances. In the first or medical section of this volume (page 58), the differences are summarised between so-called "alcoholic" neuritis and the recent cases in the North. The chief of these are (1) that the latter have not been confined to *excessive* drinkers, but have exclusively attacked consumers of beer; (2) the acute onset and rapid development, and in many cases the immediate improvement when the beer was withdrawn; (3) the general absence of certain symptoms, notably tremor and diges-

tive troubles, which are common in the alcoholic form, and the presence of special well-marked signs, such as extreme sensitiveness of the skin, "pins and needles," erythema, pigmentation, and "erythromelalgia" (erythema with pain, especially in the soles and borders of the feet), wasting, paralysis, dropping of feet and hands, anæmia, watering of the eyes; the affections being mostly symmetrical. At the same time there can be no doubt that the "alcoholic" influence has greatly accentuated the toxic action of the arsenic, and that improvement was most manifest when all kinds of alcohol were withdrawn. The author quotes the words of Dr. Judson Bury,* "The scare with regard to poisoning by arsenic has been fully justified, but surely consternation regarding poisoning by alcohol might be looked on as equally natural."

Both sexes and all ages were attacked; even infants receiving the poison from the breast, though arsenic was not detected in the milk. Among the interesting cases detailed is that of "a bonny little girl of two years" (page 50), who suffered severely; "the child's father keeps a public-house, and although so young, she was accustomed to get little 'sups' of beer" found to contain arsenic "from the customers."

The remarkable features of the epidemic are (1) that although the beer had been for some time under suspicion, the symptoms simulated so many other diseases, and assumed such a variety of types (pages 53, 61), that it was not till the end of November, 1900, that Dr. Reynolds first indicated arsenic as the cause,† followed by the chemical discovery by Kirkby a little later;‡ (2) the minute fraction of poison detected, and the small quantity of drink that was stated to have been taken in some cases, often computed to have contributed only a medicinal dose of arsenic in a week; (3) the fact that this drug had frequently been given for the very diseases that were here occasioned (page 75) with regard to (2), arsenic is known to be cumulative, and a proof was found in the fact that although traces were found in the urine, they generally disappeared when the beer was stopped, showing that the poison was not being wholly eliminated, and, secondly, that in fatal cases arsenic was present in the liver and other organs. It is also certain that the amount of liquor consumed is very rarely correctly stated.

As to the gravity of the outbreak, at least 2000 severe cases, with many minor illnesses, have occurred in the Manchester district, 66 deaths in Salford during four months attributed to the disease, 143 cases at Liverpool Infirmary, 200 or 300 at Heywood, with scattered examples in thirty-five towns, including Birmingham, Chester, Leamington, Penrith, and London, besides rural districts (page 4). Many of the cases will probably never recover (page 66). It is urged that all beverages should be subjected to chemical investigation (page 78).

A brief sketch of the treatment of the disease is given (page 71). The style of the first section requires much revision. Such words, repeatedly used, as "arsenicated," "trophic," "atrophic," "intoxication," "bed-fast," would be better replaced by "arsenical," "nutritional," "wasting," "poisoning" (in this sense), "bed-ridden" or "confined to bed;" while in "incoordination" the hyphen should be omitted. On page 45 it is said that patients "could only phonate with difficulty," meaning apparently "utter sounds." The word is not in Webster or Nuttall. The illustrations are certainly ghastly and sensational; many of them are but repetitions of one another, while the printing is not sufficiently good for the pigmentation and other details to be distinct. The second or chemical section gives the tests, results with beers and materials, a discussion of the source, a note on the excretion of the poison, and the dosage, concluding by proposing (1) "the adoption of a standard test for arsenic to which all samples of beer must conform;" (2) a regulation to be promulgated that no sulphuric acid (or hydrochloric) shall be allowed to enter into the composition of any food or drink unless it is found to be arsenic free, as tested by a standard test.

A good bibliography is appended. The book is of sanitary value, but seems designed to penetrate to the public eye. A remark on page 57 is significant:—"A patient who had attended for some time at an eye hospital, finally diagnosed her own condition (arsenical) from reading of the epidemic in the daily papers."

The Oil Chemists' Hand-book. By Erastus Hopkins, A.M., B.Sc. Published by Chapman and Hall, Limited.

This hand-book consists chiefly of elaborate and carefully-prepared tables of the general properties, adulterations, solubilities, physical and chemical constants, &c., of the oils and fats. These, we are told, are not the mere compilation of other workers' results, but are the figures obtained by the author in his own laboratory, and this claim is well borne out on examination of the different tables. Of course, such names as Allen, Wright, Archbutt, Hübl Lewkowitsch, and other notable workers in the chemistry of fats and oils are often quoted. The data given under the author's name show that they are the results of one who must have had considerable experience in the testing of oils. The tables of the general properties and adulterations of fats and oils are good and complete, and those of the physical and chemical constants have been recorded in a very thorough and exhaustive manner. The book contains valuable instructions in the preparation of solutions, &c.; for instance, on page 33 it gives the best means of preparing a colourless alcoholic volumetric solution of K H O, and of obtaining pumice stone that prevents violent ebullition on page 36. One is surprised that no account is given of the Valenta test, which is often of great value in the examination of butter fat, inasmuch as the range of the turbidity temperature is very wide and is an excellent means of judging whether margarine is present or not. The great variations between the Valenta figures recorded by different observers on page 14 is probably due, not so much to the natural difference in the samples used, but to the slight variation of the strength of acid. It is not possible to be too exact in setting the acid, and in the experience of many analysts the temperatures of turbidity given by different samples of the same oils do not vary so much as one would conclude from the table given. The work will be found a valuable book of reference to those who are engaged in the examination of oils. The theories of the processes enumerated are well explained, and the binding and type are worthy of the work and a credit to the publishers.

The seal of the Yeovil Town Council has been affixed to a draft of mortgage to the Public Works Loan Commissioners for £11,233 in connection with works of sewage disposal, and it was decided to issue tenders for the works, which, however, will cost a sum considerably in excess of that now authorised to be borrowed. The system adopted is that known as the septic treatment. In regard to two districts outside the borough area which are now connected with the Yeovil sewers and which the Rural District Council objected to being made a special drainage district, as desired by the Town Council, Judge Philbrick, Q.C., to whom the matter was referred, as arbitrator, has decided that the Rural Authority is equitably and morally bound to consent to the proposal.

Public Works.

SEWERAGE.

The Erdington District Council has resovled to construct a brick sewer in conjunction with the Bleak Hill sewer. The cost, with contingencies, will come to about £7000.

The Swanage District Council, on the recommendation of the Works Committee, has resolved to apply to the Local Government Board for leave to borrow £1160 to secure the outfall sewer.

The Camborne Surveyor estimates that the drainage schemes of Beacon, Pengegon, Wheel Gerry, &c., will cost a little over £2000. Application has been made for sanction to a loan of £2500 for these works.

Mr. J. E. Wilcox, C.E., attended a recent meeting of the Pershore District Council and explained a scheme for dealing with the sewage of Cropthorn at a cost of £1132. The proposal was referred to a committee.

At the last quarterly meeting of the Thame and Rea Drainage Board the report of the Works Committee was adopted, and the estimate of £29,821 for the drainage of four hundred acres of land, tendered by Messrs. Walker and Co., was accepted.

The Liverpool City Engineer has prepared an outline scheme for a refuse destructor on a site in Wellington-road, and this has been approved by the Health Committee, and the Engineer directed to prepare and submit detail plans and specification of the necessary work.

At the last meeting of the Newark Rural Council a letter was read from Mr. Herbert Walker, C.E., enclosing an amended scheme for the drainage of Balderton. The estimate was for £12,000, as against £10,800 for the last scheme. It was approved, and ordered to be sent to the Local Government Board for its sanction.

A specially summoned meeting of the Selby Urban District Council was held at the Town Hall, Selby, last week, for the purpose of considering what action should be taken in regard to the proposal of the Leeds Corporation to construct a sewage farm at Gateforth. There was a large attendance of members, and the decisions arrived at were unanimous. It was resolved that the Selby Urban District Council should oppose the Bill being promoted in the present session of Parliament by the Leeds Corporation.

Last week Mr. A. C. Atkinson submitted and explained to a special meeting of the Formby Parochial Committee his amended and reduced scheme for the drainage of Formby. The scheme of Mr. Atkinson, which was adopted by the Parochial Committee a few months ago, was, including all charges, estimated to cost just on £55,000, but officials of the Local Government Board pointed out that the scheme as it stood was impracticable, in so far as its cost far exceeded the borrowing powers of Formby, and it was subsequently decided by the Committee to ask Mr. Atkinson to bring his scheme within the cost of £38,000. This Mr. Atkinson intimated his willingness and ability to do, and last night he presented his scheme so amended. His estimate of the total cost of the altered scheme, including way leaves, surface-water drainage, internal drainage of private and public roads, outfall sewers, and purification works, was £37,350, and including engineer's charges and a clerk of works' salary, £39,914. Mr. Atkinson pointed out that there was only a slight diminution of the area to be drained, the chief saving being in doing without the filter beds provided by his previous scheme. It was resolved to submit the amended scheme to Mr. Wood, of Liverpool, for his expert opinion.

With reference to the Ossett sewerage scheme, the scheme of extension at the Healey outfall is now approaching its last stage. It was sanctioned by the Local Government Board without any alteration or suggestions. Possession of the land has been got, and the Corporation has instructed Messrs. Malcolm Paterson and Sam Shaw, MM. Inst. C.E., who are joint engineers, to prepare for letting the contracts. The works consist of three miles of intercepting sewers, new tanks, buildings, machinery, storm-water filter, and land filtration beds, and the Engineer's estimate, inclusive of land, is about £10,000. It is expected that the works will be let before the middle of March.

A Local Government Board inquiry has been held at Harbledown with reference to an application by the Bridge Rural District Council for sanction to borrow £5000 for the purposes of sewerage and sewage disposal for the parishes of Harbledown and St. Nicholas Hospital. Mr. Bromley, Consulting Engineer, explained the scheme. The total population of the two parishes was 868, and the total estimated quantity of sewage, taking sixteen gallons per head in any weather, would be 8000 gallons every twenty-four hours. The sewage would be pumped by means of two gas engines into bacterial tanks, where it would be dealt with. The effluent would then pass through an open channel and the subsoil in 3in. field pipes, whence it would be conveyed into the river. One pair of tanks would be provided with automatic syphons, so that they could be dealt with without an attendant. In times of storm provision was made to deal with three times the usual amount of water, while by filling the bacterial beds three times a day a double volume of sewage could be treated. Mr. Thudichum, of Messrs. Dibdin and Thudichum, consulting chemists, Westminster, called by Mr. Collard, explained some technical details of the scheme.

At a recent meeting of the Barrow Rural District Council a communication was received from Messrs. G. and F. W. Hodson, the firm employed as engineers for the Woodhouse sewerage scheme, enclosing the original plans of the scheme with drawings of additional bacteria beds, a new storm-water filter bed, and the new manholes which it had been suggested should be placed in the line of sewers. The letter stated that the filter beds as now proposed would be more than ample to deal satisfactorily with the sewage of an agricultural village such as Woodhouse. Moreover, with the view of allowing an ample margin for the dry-weather flow of sewage, they had estimated the flow at 20 gallons per head, as it had been ascertained that the Local Government Board requirements provided all that was necessary in respect of a possible increase of population. The additional cost of the scheme as amended would raise the total estimate to £7000, and it would be necessary for the Council to pass a resolution asking for sanction to borrow that amount. The Council should also give an undertaking that in the event of its being unable to renew the lease at the expiration of the twenty-one years, it would take steps to purchase the land occupied by the sewage farm, either by agreement or under the compulsory provisions of the Public Health Act. It was decided to transmit the plans to the Local Government Board, and to ask for sanction to borrow £7000.

WATER.

The Elham Rural District Council proposes carrying out a scheme for the water supply of Lyminge.

A new water tank, one of the largest in England, recently erected at Trimley for the Felixstowe Water Company, burst last week while undergoing a pressure trial. The tank was nearly full at the time, and held about 95,000 gallons (400 tons) of water.

The Dover municipal water supply yielded a profit of £4337 last year, equal to a sixpenny rate. The water supplied to the houses of £20 rating at 10s. a year, and in proportion.

The Town Clerk of Hartlepool (Mr. Bell) reported to a special meeting of the Town Council recently that the Tees Valley Water Board were, in their Parliamentary Bill of which they had given notice, asking for certain powers, the object of which was to enable them to supply any company within the boroughs without asking the consent of the Corporation. Without discussion it was agreed to approach West Hartlepool Town Council with a view to opposing the grant of any such power.

At the last monthly meeting of the Ruthin Rural Council, the clerk, Mr. R. H. Roberts, submitted the terms of the North Wales Asylum Authorities for supplying the village of Nantglyn with water from their mains. These terms were that the quantity drawn should not exceed 3000 gallons per day; that the distribution of the water shall be in the hands of the District Council; and that the rent shall be 1s. per 1000 gallons per annum. It was decided to refer the matter to a committee with a view of carrying out the scheme.

A scheme was laid before the Flamborough Parish Council last week by Mr. Eric Smith, sanitary engineer, Bridlington, for providing a better water supply for the village. The estimated cost was £3300, and though the Council was unanimously of opinion that the scheme was what was required, they considered that it would burden the ratepayers too heavily. The present rates are 4s. 6d. in the £1 per annum, and it was estimated that the scheme would bring them up to nearly 7s. in the £1. Mr. Smith was recommended to take his plans before the Bridlington Rural District Council.

The proposal to provide a new source of water supply for the borough of Basingstoke was advanced a stage at the last monthly meeting of the Town Council. The estimated cost of the suggested scheme is £16,819, and in drawing up the scheme Mr. Fitton has allowed for the possible requirements of the borough during the next twenty years. An ample and efficient water supply is one of the first requirements of a community, and it is well that the Council, before finally adopting a scheme —especially one involving such a large expenditure— should be fully assured on all points. The inhabitants of the borough will be reassured to know that the matter of a new supply has now been definitely taken up.

The Bill dealing with the future water supply of Ilkeston and Heanor has been duly lodged in accordance with the Standing Orders for introduction into Parliament next session. The preamble recites that the supply of water from the existing waterworks of the Corporation of Ilkeston and the District Council of Heanor is inadequate to meet the growing demands of the inhabitants, and it is expedient that the water in the Meerbrook Sough should be utilised, and that, for that purpose, a Board should be constituted and incorporated representing the Corporation and the District Council, with power to acquire the undertaking of the Meerbrook Sough Company, and that other additional waterworks should be authorised. The cost of constructing the proposed works, exclusive of the Ilkeston and Codnor Reservoirs, is estimated to cost the Board £106,500. By Clause 46 of the Bill, the Board is to deliver into the Ilkeston Reservoir the quantity of water to which the Corporation will be entitled, and into the Codnor Reservoir the water to which the District Council will be entitled. These reservoirs are respectively to be paid for by the Corporation and by the District Board, and, subject to this, the Water Board ask for powers to borrow £112,500 and "such sum as may be requisite" for passing this Bill through Parliament.

At the last meeting of the Langport District Council a resolution to obtain a temporary loan of £1500 for works at Curry Rivel and Drayton in connection with water supply was agreed to.

On Tuesday of this week, at the Hackney Town Hall, the Mayor presided at a town's meeting, called at the request of the Borough Council, the Hackney Tradesmen's Association, and other local bodies, to support the action of the London County Council Committee in opposing the Bill now being introduced into Parliament by the East London Water Company.

The Easingwold District Waterworks scheme has received the assent of the Local Government Board. It is for the supply of eleven villages to the Easingwold union, and includes spring collecting works and covered storage reservoir at the foot of the Hambleton Hills and some 29 miles of distributing mains. The Council has instructed its engineers, Messrs. Fairbank and Son, C.E., of York, to at once get out the necessary drawings &c., for the letting of the work.

The Burgess Hill Water Company are about to promote a Bill in Parliament authorising them to construct additional waterworks, to acquire land, and to raise further monies; and a meeting of the owners and ratepayers of Burgess Hill was held last week to consider whether consent should be given to the Urban District Council opposing the Bill. The Chairman, in his opening remarks, explained that it was necessary for the Local Authority to convene a meeting of the ratepayers before they could take any action in opposing the Water Company's Bill in Parliament. The Burgess Hill Urban District Council were of opinion, and that opinion was unanimous, that, as a general principle, the supply of water should be in the hands of the representatives of the people, and not under the control of the Water Company. Therefore they insisted, as far as they were able, upon having a compulsory purchasing clause inserted in this Bill which the Water Company had now before the House of Commons. They thought that a Water Trust should be formed, which should consist of representatives of the areas at present served by the company, viz., Ditchling, Keymer, Clayton, Hurst, and Burgess Hill. The Chairman further pointed out that the Cuckfield Rural District Council was opposing the Bill, and it also wished to have a purchasing clause inserted for its own benefit.

The arbitration in respect of the acquisition of Mrs. Crofton's two reservoirs and water-rights on Burley Moor, near Ilkley, were concluded recently. The case is peculiar in its complications, and the methods of valuation adopted by the two parties illustrate two totally different principles. The claimant's engineers assumed that their client was in the position of a vendor of water, with power to sell in bulk to competing authorities, and assessed the claim, which included manorial rights, at £11,000. On the other hand, the Council's engineers contended that there was no power to sell or even divert the water, but merely to impound it, up to, and no further than, the present capacity of the reservoirs, which are encroachments on a common with rights gained by precipitation only, and to turn such water into the stream bed. They therefore assessed the compensation for the reservoirs and water-rights on the basis of the rental received and user at the claimant's mill, amounting to about £26 or £28 yearly, arriving at a total sum of £800 or £900 only. This, they maintained, was the true principal as laid down by the Lands Clauses Acts, namely, the value to the claimant at the time of transfer. They also denied the existence of competition, even if there were power to sell water. The umpire was Mr. T. T. Wainwright, of Liverpool, and the arbitrators, Messrs. T. Fenwick and Geo. H. Crowther. The claimant's case was led by Mr. H. Johnson, C.E., and the Council's case by their engineer, Mr. Malcolm Paterson, C.E.

The South Darley Urban District Council has approved and accepted a scheme of water supply prepared by Mr. Harry W. Taylor, A.M.I.C.E., of Newcastle-on-Tyne and Birmingham. The supply will be from springs issuing from the millstone grit measures, from whence it will gravitate to the whole of the district. The estimated cost is about £3500. Application to the Local Government Board for borrowing powers will be made at once.

LIGHTING.

The Local Government Board has sanctioned the borrowing by the Llandudno District Council of £240 for gasworks purposes.

The Elland-cum-Greetland Gas Company are promoting a Bill in the coming session of Parliament to extend the powers of the company, to amend the Acts relating to it, and for other purposes.

An arbitration began last week in the Windsor Hotel, Glasgow, with reference to the claim of £7457 9s. made by the Glasgow Iron and Steel Company as compensation for about seven acres of land which have been acquired by the Corporation to enable the North British Railway Company to lay sidings into the Provan gasworks.

Owing to the gas company and the Parish Council of Wainfleet, near Skegness (Lincolnshire) not being able to agree as to the price of gas for the street lamps, the town at night is in darkness. The Council offered to pay for the gas by meter, but the company hold out for 32s. per lamp. In the meantime, whilst the dispute is pending, the inhabitants have to grope their way about the town at night as best they can.

The Southwark Borough Council is proceeding with the cable extensions in the side streets, which had not been pressed forward in consequence of the delay in securing new generating plant. The laying of the cable through Doddington-grove down to the Kennington Theatre is in progress, and on the completion of this work cables will be laid in Elephant-road, Rodney-road, Elstead-street, Alvey-street, Westmoreland-road, East-street, and a portion of Beresford-street.

A special meeting of the Omagh ratepayers has been held for the purpose of consulting as to the steps to be taken to ensure the defeat of the Bill being promoted by the gas company for extended powers. The following resolution was passed:—"That this meeting of the ratepayers of the town of Omagh approve of the action of the Urban Council in opposing the Bill of the Omagh gas company, and we strongly recommend the Gas Company to withdraw the Bill, in order to save themselves and the ratepayers the heavy expense which a contest between them would entail."

The question of the electric lighting of Maidenhead is arousing considerable interest in the town just now. An adjourned meeting of ratepayers to consider the question was held last week. A resolution proposed by Mr. F. W. Porter at the last meeting, "That in the opinion of this meeting it is inadvisable to add £25,000 to the debt of this borough in order to introduce the electric light," was debated at much length, and an amendment was submitted, "That this meeting of ratepayers respectfully requests his Worship the Mayor to convey to the Town Council its entire approval of the action hitherto taken by them in regard to the electric lighting of the borough of Maidenhead." Very divergent views were expressed as to the financial results of lighting the town with electricity, and the experience of other towns was freely quoted on both sides. The result of the meeting was most unsatisfactory, as the Mayor declared both the resolution and the amendment to be lost, but it was the general opinion that the Mayor had made a mistake and that the amendment was carried.

The Sunderland Town Council contemplates a loan of £70,000 for the establishment of a second electric lighting station and the laying down of mains.

The Gas Light and Coke Company announce a dividend for the past half-year at the rate of £4 8s. per cent. per annum, carrying forward £221,570. At the corresponding period last year the dividend was at the rate of £4 18s. per cent., £193,335 being carried forward.

The examiners of the Houses of Parliament sat last Friday for the first time this year for the purpose of hearing the proofs of compliance with the preliminary Standing Orders in the case of private Bills which it is intended to introduce in the coming session. There was no opposition in regard to the Cleveland and Durham County Electric Power Bill, and the necessary formal proofs having been given, leave was given for the introduction of the measure in the usual course.

Two important events in connection with the electric lighting of Fulham took place last week when the British Insulated Wire Company tested the final batch of cables to be laid under the streets, and the General Electric Company made a test of the steam alternators and exciters at the general station. All the tests were highly satisfactory. A large section of the borough is now practically ready for the electric light to be turned on. The work is carried out by the Borough Council, and applications have been already received from private individuals, which are equivalent to over 10,000 eight candle-power lamps.

The opinion of a meeting of owners and ratepayers was taken by the Edmonton District Council last week on their proposal to join with four surrounding parishes in promoting a Bill in Parliament to establish generating stations and to provide electrical energy. It was urged against the scheme that it involved the district in too much risk, and that as a company had been granted the powers to supply electricity in bulk, the better course would be for the Council to obtain a Provisional Order to distribute it. The meeting, however, by a large majority, upheld the proposals of the Council. A poll was demanded. The scheme is expected to cost £400,000.

Edinburgh and Leith Gas Commissioners made an official inspection of the new works at Granton last week. They were shown over the buildings by Mr. Herring, the Engineer, who explained the progress which had been made since their last visit. The first retort-house, which is to be one of several, is now well on its way, and the Engineer explained that by June twelvemonth the Commissioners will be making gas there. The sooner the works are ready the better, as a sort of hand-to-mouth process is being carried on in connection with the Edinburgh and Leith works at present. There is only available just now storage for 6½ million cubic feet, while the consumpt per day is equal to 10 millions. When the first large tank, now almost completed at Granton, and likely to be ready in a month or two, is brought into operation, this will give storage capacity for another 6½ millions, which will be carried by pipe from New-street to Granton. Even then the storage capacity will only be two or three millions beyond the daily consumpt. The first retort-house, which is expected to be in working order in eighteen months, will produce another 10 million cubic feet per day, equal to the present total output. An interesting part of the works explained to the Commissioners was the method of bringing the coal to the retorts, the whole work being done mechanically and automatically, without any handling, after landing from the steamer. Lastly, the visitors were shown that portion of the works where it is intended to treat the residual products. This, it is expected, will be the source of a very considerable revenue to the Commission, and it is hoped that it will be open in a month.

The Leatherhead Gas and Lighting Company, Limited, which was formed in 1897 to acquire the undertaking of the Leatherhead Gas Company, has deposited a Bill for next session, under which statutory powers are sought to supply gas within the parishes of Leatherhead, Mickleham, Great Bookham, Little Bookham, Effingham, Headley, and Fetcham. The capital of the parliamentary company is proposed to be £40,000, of which £19,380 represents the existing capital of the limited company, and £20,620 is additional capital proposed to be created under the powers of this Bill. The profits of the company are limited to 10 per cent. on the original capital of £19,380, and 7 per cent. on the additional capital. The maximum price for gas is not to exceed 5s. per 1000 cubic feet.

GENERAL.

The small-pox scare has cost the Carnarvon Board of Guardians £350.

The weather having suddenly become cold in the States, the epidemic of influenza is decreasing.

The Southport Corporation intends acquiring a site outside the borough, by compulsion if necessary, for the erection of an infectious diseases hospital.

A Local Government Board inquiry has been held at Portsmouth into the application of the Town Council for power to borrow £5000 for an infectious hospital, &c.

The East Barnet Valley Urban District Council has resolved to provide a hospital for its district, and is taking the requisite steps to acquire a site by compulsory purchase.

The outbreak of small-pox in Bradford is assuming serious, though at present not alarming proportions. There were sixteen patients under treatment at the Bierley Hall Hospital last week.

A Local Government Board inquiry was held at Devonport recently with reference to the Corporation's application for leave to borrow £1574 for making footpaths and improving main roads at St. Budeaux.

Messrs. J. Stone and Co., of Deptford, are introducing a system of sewer ventilation in which water is employed as a means both to extract foul gas from the sewer and to purify it before it is discharged into the atmosphere.

The Sheerness Urban District Council has under consideration the advisability of purchasing and fixing a destructor for the disposal of house refuse. The Council now pays £25 per week to a contractor for removing the refuse from the houses.

Mr. Bicknell held an inquiry at Oldham last week, on behalf of the Local Government Board, into an application by the Town Council for sanction to the borrowing of £10,230 for a new police and fire-station, and dwellings for the men, at Fawnsfield.

The London County Council will, at its next meeting, be invited to pass a supplemental vote of £25,000 for additional features to the great scheme of protection against fire which was approved by the Council in February, 1898, and which will take more than ten years to carry out.

This week the Commissioner of the Metropolitan Police (Sir E. R. C. Bradford) has again caused to be circulated the following notice:—"Whereas many persons have received injuries from falls caused by treading on orange peel, banana, and other fruit skins, on the foot pavements, the Commissioner of Police earnestly requests that all persons will assist the police in preventing, as far as possible, orange peel or other fruit skins being thrown on the pavements, and in removing any that they may observe there."

A memorial has been deposited in the Private Bill Office of the House of Commons against the Scarborough Electric Tramways Bill by the Corporation of Scarborough.

At a special meeting of the members of the Holborn Borough Council, held on Monday night, Mr. Councillor Rawlings, Q.C., in the absence of his Grace the Duke of Bedford (Mayor), presiding, a bye-law was adopted declaring any member of the Council ineligible for office unless he had ceased to be a member for at least six calendar months. The same rule is to apply to the father or son, or the partner of any father or son of a member of the Council.

At last week's meeting of the Chelsea Borough Council the Public Baths Committee reported that it proposed to pull down the present public baths, and to utilise the existing and adjoining sites for the erection of new baths, which will cost, roughly, £70,000. In the course of the discussion it was stated that there was an annual loss of £1400 on the present baths. Ultimately the recommendations of the Committee were adopted by a large majority.

The Liverpool Sanitary Sub-Committee has passed a resolution, which has been approved by the Health Committee, on the report of the City Engineer, submitting application for 219 improved sanitary ashbins for use at certain premises assessed at £10 and under, "That the bins be supplied for the premises specified in the report, and that 10s. per bin be paid to the owners towards the cost of fixing the same and reinstating the premises."

Next Tuesday the London County Council will have before it a proposal to purchase, for £16,500, the two acres of land (with a 248ft. frontage to the Caledonian-road, Islington) on which the Royal Caledonian Asylum at present stands. The directors of the orphanage are desirous of removing their charges to a rural district; and the Housing Committee of the Council propose to purchase the site under Part III. of the Act, with a view to the erection thereon of dwellings to accommodate 1400 persons.

The Nordrach Sanatorium, Banchory, Aberdeenshire, is now practically completed, and will within the next fortnight be able to accommodate its full complement of patients. It has been built on a specially-selected site—in the midst of the Corsee Woods, the surroundings of which in many respects are unequalled in this country—for the purpose of carrying out the open-air treatment of consumption and other forms of tuberculous disease. Erected at a cost of £600 per bed—there is ample accommodation for thirty-six persons—the building may be said to hold its own with even the most elaborate and extensive in Europe. The system followed is, with slight modification, the same as that of Dr. Otto Walther.

Miss Alice Busk, a member of the late Vestry of St. George the Martyr, Southwark, gave an address on Saturday last at the United Girls' Schools Mission Settlement on "Women as Sanitary Inspectors." The Mayor of Camberwell, Mr. Matthew Wallace, C.C., was in the chair, and amongst those present were members of several South London Borough Councils. Miss Busk dwelt upon the success in St. George's of the women Inspectors of houses let in lodgings, which she said had led to the decision of the borough of Southwark to appoint five women upon its sanitary staff. She advocated the employment by the new Borough Councils of women for the Inspection of workshops, laundries, wholesale warehouses, &c., where women are employed; and the appointment of fully-qualified women to teach simple hygiene and health questions in the homes of the poor. In a discussion which followed, several gentlemen spoke in favour of the appointment of women for such work.

PERSONAL.

Mr. W. B. Seldon has been appointed Town Clerk for Bideford.

Mr. J. Jones has been appointed Clerk of Works for Carmarthen.

Mr. E. P. Veale has been appointed temporary Surveyor for Dartmouth.

Dr. Bailey has been unanimously re-elected Medical Officer for Horsforth for the ensuing year.

Dr. Lloyd Roberts has been reappointed Medical Officer of Health for the urban district of Prestatyn.

Dr. Duffield, after eighteen years' service, has tendered his resignation as Medical Officer of the Kensington union.

The Local Government Board has sanctioned the appointment of Mr. J. A. Perkins as Sanitary Inspector for Feckenham.

Dr. Wm. Robertson, Medical Officer of Paisley, has been appointed to a similar position in Leith, at a salary of £400 per annum.

The Local Government Board has sanctioned the appointment of Mr. Johnson as Inspector of Nuisances for Ashbourne, at a salary of £105 per annum.

Dr. George M'Kellar, Edinburgh, has been unanimously appointed Medical Officer for Kelso, in room of Dr. Wright, resigned. The salary is £20 a year. Dr. M'Kellar intends to reside in the district and take up private practice.

Dr. Arthur Mackenzie Wilkinson, of Melbourne, son of the Rev. H. J. Wilkinson, chaplain of the Victorian Forces, Australia, has been appointed by the Government of Victoria Physician-in-extraordinary to the Duke of York during his stay at Melbourne.

Mr. Ernest Jackling, Assistant Sanitary Inspector of Maidstone, has been appointed Inspector of Nuisances to the Corporation of the city of Rochester. Upon tendering his resignation to the Maidstone Urban District Council, they unanimously directed that a testimonial, signed by the Mayor, be presented to him as a mark of their esteem and satisfaction of the manner he had discharged his duties during the seven years he had been in its service.

Dr. J. Sutherland has been unanimously appointed Medical Officer for Kirkcaldy, at a salary of £100 per annum, in connection with his duties as physician to the Fever Hospital.

The vacancy in the Medical Officership of Leith, caused by the resignation of Dr. W. Leslie Mackenzie on his appointment as Medical Superintendent under the Local Government Board, has been filled by the unanimous election of Dr. William Robertson, Medical Officer of Health for Paisley, at a salary of £400. Dr. Robertson is a man of thirty-five years of age, and is a graduate of Glasgow University, where he took his M.B., C.M., with first-class honours in medicine and surgery, in 1888. He graduated M.D. in 1891, and D.P.H. in 1892. His experience of public health work began in Perthshire, first as Medical Officer of Health for the burgh of Auchterarder, and later in a similar capacity for the city of Perth. Upon his transfer to a wider sphere of usefulness as Medical Officer for Paisley, he displayed considerable capacity and energy. He re-organised the Public Health Department of the town, and he has been consulted by the Authorities in regard to a new infectious diseases hospital, a water scheme, and the erection of a sanatorium for consumptives. He also persuaded his Local Authority to co-operate with the School Board in initiating a scheme of systematic school inspection with a view to the early detection of infectious diseases. In addition to his varied administrative experience, Dr. Robertson has written a manual on "Practical First Aid."

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2070.—Highway in Rural District: Exceptional Repairs. Appeal to County Council: Charge on Contributory Place. —"Surveyor" writes:—"The inhabitants of a parish in a rural district have petitioned the County Council respecting the condition of a district road, alleging neglect. The road in question is a moor road, with little or no traffic over it. The road has always been repaired with local stone, and is now in better repair than it has been for years. The residents, however, are determined to coat it with limestone or granite, and to have it well rolled. This, of course, will mean an enormous expense owing to the cost of material and carting, as the road is a considerable distance from a station, and is only approached by other steep roads. (1) Can the County Council compel the District Council to do this? (2) If so, can the Rural District Council charge the cost of the work upon the parish in which the road is situate, and what is the procedure?"

Answer.—A Parish Council or parish meeting may, under Sec. 16 (1) of the Local Government Act, 1894, resolve that a Rural District Council have failed to maintain and repair any highway in a good and substantial manner, and may complain to the County Council. If the latter body are satisfied after due inquiry that the District Council have so failed as respects the subject matter of the complaint, they may resolve that the duties and powers of the District Council for the purpose of the matter complained of, shall be transferred to the County Council, and they shall be transferred accordingly or by Sub-sec. 2 of the same section the County Council may make such an order as is mentioned in Sec. 299 of the Public Health Act, 1875. But if, as stated by the querist, the road has been, and is now, well repaired, the County Council will, in our opinion, refuse to make any order, and declare that the complaint is not well founded. (2) The District Council are enabled under Sec. 29, Sub-sec. (*c*) of the Local Government Act, 1894, to charge highway expenses under exceptional circumstances on a contributory place as a highway board has in respect of any area under Sec. 7 of the Highways and Locomotives (Amendment) Act, 1878.

2071.—Infectious Hospital: Recovery of Cost of Maintenance. Parents not Liable in Respect of Cost of Children.—"Clerk" writes:—"My Council is a subscriber to your journal. I am desirous of being informed of any case where an Urban Authority has claimed through the County-court to recover the cost of maintenance in a hospital of a patient under Section 132 of the Act of 1875."

Answer.—We are unable to refer our correspondent to any report of County-court proceedings for the recovery of cost of maintenance of patients in infectious hospitals. Doubtless some of our readers may be able to assist with information, as such reports generally appear in local newspapers only. The Council may recover the debt in a Court of civil jurisdiction, such as the High Court or the County-court. It cannot be recovered summarily before magistrates. And in any case the debt can be recovered only from the patient himself, not from his parents. In Hull Corporation *v.* Maclaren, Q.B.D., May 20th, 1898, the County-court judge had given judgment against the father of a child who had been treated at a hospital belonging to the Corporation for £6 7*s.* in respect of the child's maintenance. This judgment was, however, reversed by the High Court. Ridley, J., said, "I am of opinion that the decision of the learned County-court judge cannot be upheld. It is clear from the note which the learned judge has supplied to us that he was under the impression that the liability for the maintenance of the child was cast on the father by the Public Health Act, 1875. But from a perusal of Section 132, on which the Corporation relied, it is evident that such liability is cast on the patient only. The real question which should have been considered below was whether apart from the statute the parent had contracted either expressly or by implication to pay for the maintenance of his child in the hospital. But that question was not considered by the learned judge, nor are we entitled to consider it here, though I think it is clear that the parent did not agree to pay for the maintenance of the child. The real point was not considered; under the statute no such liability is cast on the parent. The appeal must succeed."

2072.—Public Health Highway Acts: Editions Recommended.—"Surveyor" writes:—"Would you kindly advise on the following: (1) Is there a collection of the Acts of Parliament such as Highway, &c., Acts, other than the Public Health Acts, which are required by a Surveyor to an Urban District Council? (2) What Acts, outside of the Public Health Acts (which I have at present in Knight and Co.'s edition) are required,

and what would be their approximate cost, such as Building in Streets Acts; Towns Improvement Clauses Acts; Tramways Act, 1870; Waterworks Clauses Acts, Private Street Works Acts, &c.?"

Answer.—For municipal engineers and surveyors in practice who require to obtain a sound knowledge—which is extremely essential for their own success, and the proper and efficient discharge of their duties—of the Public Health and other Acts under which they have to work, there are two publications which are indispensable, viz., Macmorran's "Public Health Acts," in two vols., price 67s. 6d., post free 55s. 6d., and Pratt's "Law of Highways," price 32s. 6d., post free 26s. 9d. These volumes contain all the Acts mentioned by the querist, and are fully annotated, enabling the lay reader to interpret their meaning with a degree of satisfaction and confidence which is not possible by the perusal of statutes such as those he possesses and suggests which are not annotated. Handford and Mackenzie's "Model Bye-laws," two vols., price 25s., post free 20s. 9d., is also a desirable and necessary publication, which should be in the library of a municipal surveyor. Any of the books may be obtained from the office of this journal.

2073.—Burgh Police (Scotland) Act, 1892: What is "Sufficient" Repair?—"Manu Forti" writes:—"A Town Council is about to pass a resolution in terms of Sec. 142 of the Burgh Police (Scotland) Act, 1892, to undertake the maintenance and repair of all footways in the burgh. Can they by virtue of that resolution order a proprietor to lay down granolithic paving in substitution for a gravel footpath now existing, or can they only order the proprietor to 'repair' the gravel footpath? (2) On the other hand, can a Town Council, ignoring Sec. 142, proceed in terms of Sec. 141 to require all owners of footpaths in the burgh to construct footpaths to their satisfaction, and if so, what purpose does Sec. 142 serve? (3) Can a Town Council in a Scotch burgh, where the footpaths have not been taken over in terms of Sec. 141 or 142 of the Act, ask the owners thereof to repair the same without becoming responsible thereafter for their maintenance, and if so, by what Act?"

Answer.—In our opinion, although the matter is one which is not entirely free from doubt, the expression "to have their foot pavements before their properties put in a sufficient state of repair," includes the paving in such a manner as to constitute it in such a "sufficient state of repair" as the Commissioners may decide, and this, we think, is borne out by Sec. 143, which is a corollary to it, which gives the "person whose property is affected, and who thinks himself aggrieved, to appeal to the Sheriff as regards the making, altering, paving, or causewaying, and maintaining streets and foot pavements." (2) The provisions of Sec. 141 apply to the case of any new street; or any other individual street in the burgh which the Commissioners may determine at an ordinary meeting of the Council, shall have the footways well and sufficiently paved. In Sec. 142, however, the provisions can only be put in force "by resolution at a meeting *specially called for the purpose* to undertake the maintenance and repair of *all* the footways of the burgh." (3) Yes. See Sec. 135 of the same Act.

2074.—Drain or Sewer: Combined Drain Emptying into a Cesspool Not a Sewer.—"T. E. W." writes:—"An owner requires me to clear a drain which is choked. The drain empties into a cesspool which we are bound to empty, and which I have had done. The owner maintains, as there are eight houses connected to the drain, it becomes a sewer and repairable by the Council. Inasmuch, however, as it is not connected to the public sewer, I maintain it is not repairable by my Council. Will you kindly advise me on the subject?"

Answer.—There is, in our opinion, no obligation on the part of the Local Authority to cleanse the drain, as it is not a sewer which is vested in them. In Meader *v.* West Cowes Local Board 1892, 3 ch. 218; 61 L.J. ch. 561; 40 W.R. 676, Lopes, L.J., held that a thing which does not carry away sewage cannot properly be called a sewer, and Lord Coleridge, C.J., in that case took the same view. Accordingly a pipe which carries the sewage of two or more houses into a cesspool is not a sewer within the Public Health Acts which vests in the Local Authority. The decision in this case was followed in Button *v.* Tottenham Urban District Council, 62, J.P., 423.

2075.—Bye-laws as to Drainage of Existing Houses.—"A. J. M." writes:—"I should be glad if you could give me the name of any Urban Authority who have adopted a good set of bye-laws regulating the construction of drains to old or existing houses."

Answer.—As we pointed out in our reply to Query 2067, in our issue of the 17th inst., the Urban District Council of Carshalton, Surrey, have adopted bye-laws with respect to the drainage of existing buildings.

J. & M. CRAIG, Ltd., KILMARNOCK

A SUGGESTED METHOD OF PREVENTING WATER-BORNE ENTERIC FEVER AMONGST ARMIES IN THE FIELD.*

By Louis Parkes, M.D., D.P.H., Medical Officer of Health for Chelsea, and Samuel Rideal, D.Sc., F.I.C.

(*Concluded from page* 64).

As regards acidity, the same amount of acid, as measured by decinormal soda solution, appears to be required to produce a similar result in nitro-hydrochloric acid (dilute B.P.), and sulphuric acid (dilute B.P.), sodium bisulphate in the proportion of one gramme to the pint contains about two and a-half times the acidity of twenty minims of sulphuric acid (dilute B.P.). If anything, the nitro-hydrochloric acid appears to be most efficient *quâ* acidity; and this is intelligible when it is recollected that there is likely to be a small quantity of free chlorine in this acid—chlorine having very marked disinfectant properties. The citric and tartaric acids, to be efficient, must contain at least three times the amount of acid, as measured by decinormal soda solution, that is sufficient for nitro-hydrochloric and sulphuric acids.

Experimental trials were also made with acid sodium phosphate, and with sodium sulphovinate, but they were found to be inefficient.

In order to show that the presence of 1 c.c. of the acid solution in the agar does not affect the capacity for growth of the *Bacillus typhosus*, an experiment was made by adding some of the blank infected water directly to agar tubes containing 1 c.c. of the acid solution. After twenty-four hours incubation, at 37 deg. Cent., the plates showed very numerous colonies in every instance.

Experiment II.

Eight hundred cubic centimetres of boiled tap water infected with two drops of a twenty-four hour broth culture of *Bacillus typhosus* at 37 deg. Cent.

Agar plate cultures made with 0·2 c.c. of the mixture.	Results obtained after contact of infected water with acid solution for periods of	
	5 min.	15 min.
Sodium Bisulphate—		
1 gramme per pint of infected water	6 cols.	B. Typh. killed
Tartaric Acid—		
1 gramme per pint of infected water	120 cols.	50 cols.

The tap water was boiled, and then cooled before infecting, in order to kill the few organisms present capable of growth at blood-heat in the agar, and so facilitate the subsequent counting of the typhoid colonies.

Experiment II. is confirmatory of Experiment I., but the typhoid bacilli in this experiment were either more numerous or more resistant than in Experiment I., as the results are not quite so good. The water was infected with two pipette drops of the broth culture instead of with one; on the other hand, only one-fifth c.c. was used for plating the agar, instead of 1 c.c. as in Experiment I.

The inferiority of tartaric acid to sodium bisulphate (equal strengths of each being used) is well shown in this table.

Experiment III.

One hundred cubic centimetres of boiled tap water infected with 1 c.c. (approximately 20 drops) of a twenty-four hour broth culture of *Bacillus typhosus* at 37 deg. Cent.

Sub-cultures made into broth tubes (incubated for forty-eight hours) by three platinum wire loopfuls, after contact of infected water with acid solution for periods of—

—	7½ mins.	15 mins.	30 mins.	45 mins.	60 mins.	2 hours.
Sodium Bisulphate.						
1 grm. per pt. of infected water	+	+	+	−		
0·75 grm. ditto...			+	+	±*	
0·5 grm. ditto				−	−	+
Tartaric Acid.						
1 grm. per pt. of infected water	+	+	+	+		
0·75 grm. ditto...			+	+	+	
0·5 grm. ditto				+	+	+
Sulphuric Acid, dilute B.P.						
20 minims per pt. of infected water	+	+	+	+		
15 minims ditto			+	+	+	
10 minims ditto				+	+	+

* Growth after forty-eight hours somewhat inhibited in the sub-culture.

Experiment III. shows that when a water is heavily infected with culture of *Bacillus typhosus* (to the extent of one per cent.), the time of contact must be very materially increased to prevent subsequent growth of the bacillus in broth. Sodium bisulphate (one gramme per pint of infected water) is then only effective if contact has been made for forty-five minutes. Tartaric and sulphuric acids in similar strengths did not prevent the subsequent growth of the bacillus after forty-five minutes contact.

Experiment IV.

Five hundred cubic centimetres of boiled tap water infected with one drop of a twenty-four hour broth culture of *Bacillus typhosus*. Four different cultures were used, marked respectively J 1, R, B, and M, thus making four infected waters. The one marked J 1 was found to contain 9120 cols. of *Bacillus typhosus* per 1 c.c.

Agar plate cultures made with 1 c.c. of the mixture.	Results obtained after contact of infected water with acid solution for periods of				
	3 mins.	7 mins.	10 mins.	15 mins.	30 mins.
Sodium Bisulphate.					
1 grm. per pt. of infected water, J 1	Numerous, but greatly reduced*	50	3	0	0
Ditto, R.	Very numerous	200	24	0	0
Ditto, B.	Numerous	140	14	0	0
Ditto, M.	Very numerous	200	Plate spoilt	0	0

* Greatly reduced when compared with the blank (control experiment).

Experiment IV. was made to ascertain if any variation arose from the use of broth cultures of *Bacillus typhosus* of different origins. The one marked J 1 was used in the preceding experiments. The others, marked R, B. M, were kindly forwarded to us by Dr. Savage, of Cardiff,

The results, on the whole, show but comparatively little divergence, having regard to the fact that the waters were infected with four different cultures of varying degrees of remoteness from their original stocks.

It may be used as an argument against the deductions which we think that we are entitled to draw from our experiments, that in broth cultures of *Bacillus typhosus* the organisms are living under artificial conditions, and that waters infected by natural means derive the living virus directly from the fæces or urine of an enteric fever patient. There would be reason in such

* A paper read before Epidemiological Society, Friday, January 18th, 1901.

a line of argument, if it could be shown that the bacilli on emerging from the human body are more resistant to adverse agencies, such as our chemical solutions are, than those which have been cultured and sub-cultured in broth.

That this is not generally held to be so is now recognised; for the probabilities are in favour of the view that pathogenic organisms by propagation in artificial media outside the human body tend to become saprophytic; and whilst very probably losing in virulence, yet acquire higher resistant powers to agencies affecting their life and growth than they ever possessed when they flourished as parasites in the human body. The two properties of virulence and resistance to external destructive agencies must be clearly differentiated. We think there is every probability that the agency which proves fatal to the sub-cultured bacilli would have an equal, if not greater, effect upon organisms of high virulence immediately derived from the excreta of an enteric fever patient.

EXPERIMENT V.

(1) Seven hundred and fifty cubic centimetres of boiled tap water infected with three drops of a twenty-four-hour broth culture of *Bacillus typhosus* (approximately 0·2 of broth culture to 1000 of water—1 c.c. yielded 12,000 colonies).

(2) Five hundred cubic centimetres of boiled tap water infected with five drops of a twenty-four-hour broth culture of *Bacillus typhosus* (approximately 0·5 of broth culture to 1000 of water).

(3) Four hundred cubic centimetres of boiled tap water infected with eight drops of a twenty-four-hour broth culture of *Bacillus typhosus* (approximately 1·0 of broth culture to 1000 of water—1 c.c. yielded 52,000 colonies).

Agar plate cultures made with 1 c.c. of the mixture.	Results obtained after contact of infected waters (1, 2, 3), with acid solution for periods of :—	
	15 min.	22 min.
Sodium bisulphate. 1 grm. per pt. of infected water ...	Sterile.	—
Three 5-grain tabloids* per pt. of infected water	100 cols.	2 cols.

* The tabloid took seven minutes to dissolve. It only contains 73 per cent. of the theoretical amount of acidity a 5-grain tabloid of sodium bisulphate should contain, showing that about one-quarter of the tabloid is made with some inert substance. The experiment was made with No. 1 water only.

Experiment V. shows that sodium bisulphate in the proportion of one gramme per pint is effective after fifteen minutes' contact, even for waters containing as many as 50,000 colonies of *Bacillus typhosus* per 1 c.c. The tabloid of the same substance takes some minutes to dissolve; and, as it contains some twenty-seven per cent. of inert matter, it is not surprising that the results obtained with it are less successful than those obtained with the pure chemical.

This experiment leads us to the consideration of the dose of the poison, or the number of bacilli which must be imbibed in order to induce the disease—a subject on which practically nothing certain is known.

On the one hand, waters which were believed on well-founded grounds to have been productive of outbreaks of enteric fever have been bacterioscopically examined—usually several weeks, however, after the period at which they were supposed to be infective—and no typhoid bacilli have been isolated. On the other hand, it is now known that in some 25 per cent. of all cases of enteric fever the urine, during the later stages of the disease, and during a prolonged convalescence, may be teeming with *Bacillus typhosus*, in some cases being actually turbid from the presence of many millions of these organisms per c.c. It will be easily understood how, if but a small quantity of such urine finds its way into drinking water, such water may become infected with bacilli exceeding in numbers per c.c. any of those which have been artificially manufactured in the laboratory during the course of our research; although from Experiment III. it appears that sodium bisulphate has a considerable effect, even when pollution to the extent of 1 per cent. has occurred.

It is reassuring, however, to know that it is only in about 5 per cent. of these cases of infective urine (P. Horton Smith, *Lancet*, May 20th, 1899) that this liquid is rendered turbid by the presence of the bacilli; so that the condition is only actually present in about 1·25 per cent. of all cases of enteric fever. It is very doubtful also if the bowel excreta at any time contain bacilli at all comparable in numbers with those now known to be occasionally present in the urine of convalescing patients.

On the whole, it would appear as if we might be justified in assuming that (1) water naturally infected with the virus of the disease does not contain so very large a proportion of the bacillus; that (2) this organism is not by any means resistant to acids or other weak disinfectants; and (3) that the use of such simple means as here suggested by us, for combating infection, has possibly a future before it, more especially under conditions of life where the means of sterilisation by boiling and filtration are not readily available.

As regards the use of sodium bisulphate during a campaign, we would recommend its being employed in the form of tabloids—each tabloid to contain five grains of the bisulphate. The tabloids should be made to dissolve quickly in water, and for this purpose the minimum quantity of gum arabic or other adhesive substance should be used in their manufacture. The tabloids should be put up in well-made light metallic boxes, to hold about a quarter of a pound weight—equivalent to about 350 tabloids—enough to sterilise over 100 pints of water at the rate of three per pint. One of these boxes should be carried by every soldier in his haversack. Supposing the soldier to consume five pints a day when on the march, the quarter of a pound tin would suffice for nearly three weeks, at the end of which time he will probably again be in touch with his transport.

Instructions should be given by the Medical Officer to the rank-and-file as to the use of the tabloids, and more especially as to the desirability of allowing all contaminated water to remain in contact with the dissolved tabloids for at least fifteen minutes before being consumed. The soldier of the future, it is now recognised, must have more intelligence and more individual initiative; and this should extend as much to the care of his health, when in camp or on the march, as to his action on the battlefield.

The acid tabloids will be found to render the water much more effective in slaking thirst, and there will, in consequence, be less inclination to drink large quantities of water, a smaller quantity when acidulated sufficing. The tabloids may also be used as thirst lozenges when water is scarce, and will, we believe, be found to be useful by promoting the secretion of saliva, and so preventing parching of the mouth.

We are informed by an officer, recently returned from the war, that he found the "thirst lozenges" he took out with him from England most useful. There was an immense demand for them by the men of his company; and the men who took them were satisfied with much less water than those who failed to obtain any.

In a country such as South Africa, where the heat of the day is generally very great, and water is scarce and often polluted, it seems very desirable that something should be done, both to diminish the inevitable sufferings of our soldiers from thirst and to protect them from the ravages of water-borne disease.

THE VENTILATION OF SEWERS.*

By H. Gilbert Whyatt, A.M.I.C.E., Mem. San. Inst., Borough Engineer, Grimsby.

(*Concluded from page* 46.)

The use of tall chimney shafts.—Many towns have attempted to ventilate the sewers by connecting them with tall chimney shafts placed above the ground—either special chimney shafts built for the purpose with coal or coke furnaces always burning at the bottom, or by connections with factory chimneys actually in use, in both of which cases there would be powerful draughts.

It was supposed that the strong draughts thus produced would draw the noxious sewer air from all the sewers for very considerable distances, and this expedient if successful would have been a most excellent and commendable sanitary improvement in connection with the sewage of towns, as all the foul air from the sewers would have been discharged at a considerable height above the ground. It has always been found, however, that the ventilating effect of any such shaft is only local, that is to say, the air to supply the draught is drawn from the nearest inlet, and hence has no effect, except in a very short length of the sewer.

It will be seen from the tabulation in Appendix No. 1, that only one town has made any extensive use of chimney shafts, and the Borough Engineer of Gloucester expresses the opinion that "they are not worth the extra expense over an ordinary six-inch shaft."

The use of house chimneys.—It has been suggested by one or two sanitary engineers to use house chimneys for the purpose of ventilating sewers. I do not think that this would be at all advisable. The ordinary house chimney is so poorly pointed and pargeted on the inside that there would be great risk of sewer gas leaking through into the building.

One such instance occurred in 1896, where the King's Norton Rural District Council connected a ventilating shaft into a chimney, the owner died, and the executors brought an action for damages. The jury found that the Local Authority had been negligent, that sewer gas had escaped into the house, and that the fatal illness of the gentleman resulted therefrom; and they found for the plaintiffs damages £3500.

Sewer gas destructors.—Some years ago a patent was brought out for drawing out sewer air from the sewers and cremating it in a little furnace constructed at the bottom of a lamp pillar. They are constructed to burn about 8 cubic feet of gas per hour, and at 2s. 6d. per 1000 cubic feet this represents an annual outlay of nearly £9. Capitalising this at thirty years, we have a total of £270, to which should be added the cost of the lamp, say £15, making each sewer gas destructor equal in cost to a lump sum payment of £285 for dealing with the sewer gas at that particular point.

Many towns have fitted one or two as an experiment, but owing to their great cost their use in many cases has been abandoned.

Lamp columns as ventilators.—It has been suggested that each lamp pillar should be so arranged as to be a tube connected with the sewers and acting as a ventilator. I find, however, on inquiry from Mr. W. A. Vignoles, the Borough Electrical Engineer, that there is some electrical apparatus inside of each of the lamp pillars about to be erected by his committee. This would be likely to be very injuriously affected by the sewer gases, and I think he would therefore recommend his committee not to allow the poles to be used for this purpose.

In Southport over 200 lamp posts are used as sewer vents, and are so generally unnoticeable that no complaint of nuisance arising from them is ever made.

I suggest that your committee should consider whether some of the lamps in those streets which are not to be lighted by electricity should not be altered so as to ventilate the sewer in the street.

Property owners' objection to vent shafts.—In many towns the property owners object to vent shafts from sewers being fixed to their property, but I have so far found that this objection is not met with in Grimsby. In some towns where a manhole is put opposite property a ventilating cover is fixed, unless the adjoining owner will give consent for a vent shaft being fixed to his property; and in other towns where a nuisance from a manhole is complained of, the manhole is only closed upon condition that the adjoining owner allows a vent shaft to be erected on his property.

Ventilation of drain between sewer and trap.—I have already mentioned that in many cases in Grimsby this particular length of pipe becomes "air-locked," or tide-locked, and I find on perusal of the reports of the engineers of other boroughs that the same difficulty is met with elsewhere. This difficulty can be got over by placing a vent pipe on this length of drain carried up above the adjoining buildings, and from the replies to queries it appears that in Torquay over 2000 of these have now been erected.

I have suggested this pipe to various builders in Grimsby since I took up the duties here, and it has been in five cases erected by them without any objection, whilst the erection of thirteen others is now in progress. If this could be generally insisted upon, it would be a great benefit to the sewers of Grimsby. I think that, in view of the present powers possessed by the Corporation, it can be everywhere insisted upon in the future.

It must be admitted that since the duty of ventilating the sewers devolves upon the Corporation under the section quoted above, the cost thereof must also be borne by the Corporation; but these lengths between the sewer and the trap are single private drains, and the duty of ventilation rests upon the owner.

Rust pockets.—In connection with all ventilation shafts it is impossible to paint them internally after they are fixed; and, consequently, after a year or two a large amount of rust forms on the inside, and falls to the bottom. It is the universal experience of Sanitary Engineers that vent pipes after a few years cease to act, unless an adequate rust pocket at the base is constructed. In all pipes erected by the Corporation it is easy to arrange for this being done.

I suggest that pressure be put upon builders of property to construct these rust pockets at the bottom of each vent shaft, both on the vent to be placed in the length of drain between the trap and the sewer, and on the vent at the upper end of each house drain; and in view of the powers possessed by the Corporation I think this can be done.

The flushing of sewers.—The importance of frequent and copious flushing, so as to effect the removal of silt and putrefying sediment as soon as possible, cannot be over-rated. It has been suggested that the flushing caused by heavy rain storms is more effective than that done by the Corporation, because in times of storm sand and grit are washed into the sewers with the rain and scour the interior of the pipes; and hence it is that after heavy rains surface ventilators are less offensive than at other times; but it is equally probable that a heavy rain storm gives an adequate flush to the intercepting trap on the house drains, and thus all semi-decomposed sewage is removed out of the sewers.

Present flushing arrangements.—The gradients of the sewers in Grimsby are very flat, and consequently very few of the sewers are self-cleansing. It has been found necessary, therefore, to make special arrangements for flushing the sewers in order to wash out the sediment and keep them clean. A list of them will be found in Appendix No. 4. The majority of these require the attendance of a workman, and therefore it is possible for the flush always to be made when the tide is low, and

* Report to Special Sub-committee of the Council, county borough of Grimsby.

the penstock doors at the sewage pumping station are open.

The automatic flushing tank at the corner of Stirling-street and Weelsby-street is supplied with water from the Corporation distributing mains, and is arranged to go off at intervals, irrespective of whether the tide is high or low, or whether the penstock doors at Riby-street are closed or open. I suggest that it should be part of a workman's duties to attend at this tank at say 3½ hours after high tide to open the valve, so that the tank may be discharged at half-hourly or hourly intervals, and that he should entirely close the valve 3½ hours before the next high tide; so that on the average there will be 4 hours' flushing at short intervals out of every 12. It is possibly not necessary for this to occur during the night, and it is simply a question for your committee to decide as to whether they agree to pay extra for night work.

The flushing places in connection with the Haven consist of pipes with valves connected from the Haven into the sewer; the idea of the arrangement being this, the water in the Haven is directly connected to the sea at high tide when the Union Dock gates are opened; immediately after high tide these gates are closed, and the water is held up. About four hours after high tide the Corporation workmen open the valves and allow sufficient quantities to flow from the Haven into the sewers. But it is found on the majority of days in the month, that, owing to the large traffic through the Union Dock, and the number of times the lock has to be opened for the passage of vessels, the water in the Haven has sunk to so low a level as to be below the valves, and hence it is impossible for the flushing to take place. I suggest that at each of these places a tank should be constructed, so arranged as to automatically fill at high tide from the Haven, and to remain full, although the water in the Haven lowers, and then at about four hours after high tide the workman by opening an outlet valve may flush the sewers. This would necessitate the construction of five tanks of 5000 gallons capacity.

In Lambert-road there is a fresh-water pipe from the Park Lake, from which it is possible by closing a penstock to divert the water into the Lambert-road sewer, and to flush Ainslie-street; and also a pipe from the fish-pond in the grounds of the Abbey, from which it is possible, by opening penstocks, to flush either westwards along Lambert-road and the Abbey Park-road sewer, or eastwards to accomplish the same flush as from the Park overflow sewer.

In Heneage-street, near the corner of Margaret-street, there is a fresh-water culvert across the sewer, and here, by placing a shutter in the fresh-water culvert and opening a penstock in the sewer, it is possible to flush the main sewer along Heneage-street. There are three other positions, as seen from Appendix No. 4, where a similar arrangement exists.

There are thirty-four places where hydrants are placed upon the Corporation water pipes, and by opening these the sewers can be flushed with the subsoil water pumped into the tank at the Riby-street pumping station.

In addition to these fixed points, the Corporation possesses a wrought iron flushing tank on wheels, containing about six tons of water, or 1340 gallons. This tank can be wheeled to any part of the borough, filled with water, and made to discharge into any sewer or drain to which access can be obtained through gullies, ventilators, manholes, or by openings specially made for the purpose.

Syphons and flap valves in sewers.—It has been found necessary at several places in the sewers of Grimsby to carry the main sewers under the fresh-water culverts by means of syphons, and thus at each end of the syphon there is practically a "dead end" so far as the passage of air is concerned.

At other places flap valves have been placed at the ends of sewers discharging into other sewers, in order to prevent any flood in the main sewer backing up into the tributary sewer. These likewise form a "dead end." I suggest that in each of these cases a vent shaft should be put in as near the "dead end" as possible. A list of these places will be found in Appendix No. 2.

The Pyewipe outfall and Haycroft drain.—Previous to the construction of the Alexandra Dock the Haycroft drain meandered through the West Marsh across the site of the dock, discharging itself close to the ship-building yards; but when the Alexandra Dock was constructed this was diverted at the expense of the railway company, and a new road was made on the west boundary of the borough with the main sewer running down the centre of it. I understand that this has very few manholes upon it, and that these have closed covers.

At the outfall there are doors hung in the ordinary way upon hinges, so that at low tide the flow of water along the outfall keeps the doors open; and when the tide rises above the level of the water in the culvert the tide flows in and the current closes the doors. The result is this, that when the wind is from the north-west, north, or north-east, and these doors are open, the wind blows into and along the culvert, and the whole of the foul odours in the culvert are discharged in the neighbourhood of Lord-street, Lime-street, and Macaulay-street. When the wind is in any other direction this stream of air through the culvert does not exist. When the gates at the outfall are shut and the water is backed up in the culvert by the closed doors and rising tide, the whole of the air displaced by the water is driven out and discharged in the district just named. Your sub-committee noticed this effect on the occasion of their visit on the 10th instant. I suggest that an arrangement should be made with the railway company for the erection of adequate ventilation shafts at intervals along the length of this sewer, and that an attempt should be made to utilise the chimney of the biscuit factory (lately burnt down), which is close to the line of drain. A properly-constructed curtain should be placed in the sewer in the vicinity of Lime-street, in order to prevent the sewer gas being discharged in this neighbourhood.

Having laid the whole of the facts of the case before his Council as above, Mr. Whyatt makes the following recommendations:—(1) All manholes which have been complained of during the last two or three years to be at once closed, and to have a shaft erected communicating therewith. Where possible this shaft should be placed on the sunny side of the street, in order that as far as possible the heat of the sun may assist the up-draught. (2) In those cases where the sewers are syphoned under culverts, or where flap valves are put in to act as gas checks and regulators, a shaft to be at once placed at each side of the syphon or valve. (3) A shaft to be placed at every "dead end" in the sewers. (4) Where manholes are complained of in the future, close them only upon facilities being given for the erection of a shaft on the adjoining property. (5) To insist upon a vent shaft being placed on the sewer side of each intercepting trap (such shaft to be provided with a rust pocket) in order to vent the length of drain pipe between the trap and the sewer. (6) To at once arrange for the ventilation of the Pyewipe outfall, so as to prevent the whole of the air of this mile of sewer being discharged in the neighbourhood of Lime-street, Lord-street, and Macaulay-street. (7) To alter such flushing arrangements as now exist, so that they shall not discharge into the sewers during the periods when the penstock doors are closed at the sewage pumping station in Riby-street. (8) To construct underground tanks or cisterns alongside the Haven, so arranged as to automatically fill from the Haven at high tide, and to be discharged by an attendant at 3½ or 4 hours after high tide.

Important Notice.—Will any reader who may have sent money to a Mr. Ashton, a tutor for Sanitary Examinations, kindly communicate with the editor.

ARSENIC IN BEER.*

(*Concluded from page* 70.)

PROCEDURE ON DISCOVERY OF ARSENICAL SAMPLES.

From time to time, as the inquiry proceeded and the analytical work progressed, the County Analyst notified the discovery of any arsenical samples to the Clerk of the County Council, who at once communicated with the sellers, cautioning them against the serious risks they ran unless they immediately ceased to sell the arsenical beer. It will be remembered that, after carefully considering the question, the Committee decided not to take proceedings under the Act unless in the unlikely event of a second offence, or if any person, after a reasonable time, was detected selling arsenical beer. Of course, now that the circumstances are well known to every brewer and publican in the kingdom, no leniency can be looked for if such beer is again discovered to be on sale.

It followed, as a matter of course, that the official caution sent to the beer-seller was passed on to the brewer, but, irrespective of this, I thought it advisable to call personally upon the implicated brewers in order to ascertain, if possible, what steps they had taken, or proposed to take, to stop the sale or consumption of all beer which had been brewed with the particular glucose which, by this time, was known to be the cause of the trouble. This was the only information which, in the first instance, I hoped to obtain, and I must say I approached the brewers with a considerable amount of diffidence, not knowing, under the circumstances, how my visit might be received. As it turned out, however, I was received, without exception, with the utmost courtesy, and, besides obtaining the comparatively limited information sought for, I was supplied with further details which proved of the utmost value in elucidating certain circumstances attending the distribution of the cases of poisoning throughout the county which otherwise would have remained obscure.

I may here state that, with one exception, the implicated brewers had used glucose supplied by Messrs. Bostock and Co. The exception was one of the breweries in an adjoining county, and upon further inquiry, I found that the public-house where the sample was obtained was not a tied house, and the probability is that the beer sold to the Inspector had been obtained from some other source. At any rate, the brewer who was supposed to be implicated assured me that he had only once used "Bostock" glucose, and that the small stock he had of it was exhausted more than twelve months ago. He also showed me the certificate of a well-known chemist testifying to the purity of all his beers and brewing materials.

STEPS TAKEN TO STOP THE SALE OF ARSENICAL BEER.

As regards the implicated brewers, I ascertained from each, step by step, the measures taken to put a stop to the sale of the arsenical beer. They also informed me as to the exact dates on which the steps were taken, and I had opportunities of verifying the information in most cases by documentary evidence in the shape of letters, telegrams, &c.

I need not go into detail regarding the steps which were taken by each firm, as a general account will, no doubt, be considered sufficient, especially as I am in a position to state that in every case prompt action was taken, and I believe time will prove that the desired result has been attained.

It appears that soon after the scare arose, Messrs. Bostock and Co. communicated with some of their customers, asking them to discontinue brewing with the glucose they had supplied, as they had reason to doubt its purity, and that they would write again. After two or three days' interval, a second communication was received to the effect that the glucose might be used with safety, and immediately following this a third letter to say that the glucose, after all, was found to be arsenical, and that they would be glad to have it returned. I am glad to say that the brewers did not await the ultimate outcome of these vacillating communications, but took steps to satisfy themselves regarding the quality of the glucose by obtaining independent analyses, with the result that in every case the glucose was pronounced to be arsenical.

Upon this, prompt steps were taken to recall the arsenical beer, but as may be imagined, this could not be accomplished in a day. In some cases the beer was immediately discharged into the sewers either on the spot or at the brewery. In other cases it was locked up either at the public-houses or at the brewery, to be destroyed in the presence of the Excise Officers, in the hope that the duty charged upon it will ultimately be rebated. As far as possible, private customers were also communicated with, and on the whole, from what I could ascertain, I believe every effort was made to put a stop to the consumption of the arsenical beer, and at the present time I feel pretty confident that none is on sale. Possibly, for a little time minute traces of arsenic may still be found in beers, for the reason suggested by the County Analyst that the brewing vessels may impart slight contamination to the beers that are now being brewed from pure materials—in fact he suggests that this is the probable explanation of the traces of arsenic present in seven of the samples analysed—time, however, will remedy this, and, meanwhile, the amount of arsenic which can thus be imparted to beer is so infinitesimal that it may be disregarded from a health point of view.

AMOUNT OF GLUCOSE USED IN BREWING.

Having regard to the fact that the use of arsenical glucose was the sole cause of the trouble, it is evident that the degree of contamination of the beer would vary in accordance with the amount of such glucose used by different brewers. In this respect the practice varies considerably, and the quantity has no fixed relationship to the amount of malt used. Among those brewers who have been good enough to supply me with the information, I find that the proportion of glucose used to malt varies from 12 to 33 per cent., and that the actual amount of glucose, say per barrel of beer, varies from 6·6 lb. to 22·4 lb., and this, when reduced to gallons, gives a range of from 2·9 oz. to 9·9 oz.

Such is the practice in the case of beers brewed for ordinary public-house consumption, but the reason for the extreme diversity in the amount of glucose used by different brewers is not very apparent. The brewers state that they brew to suit their customers, whose tastes are said to differ in different localities. In fact, one brewer informed me that the "fashion" in this respect differs so much, even in adjoining districts, that he is obliged to brew two distinct and very different qualities of beer to satisfy the wants of two artisan communities situated only a mile or two apart.

In the case of three of the implicated brewers, however, another factor came into play which still further accentuated the difference in degree of contamination of beers brewed by firms using Bostock's glucose. The three brewers in question had been in the habit of using, in the same brew, a mixture of glucoses, all of which, with the exception of Bostock's, were free from arsenic, and thus, in accordance with the total amount of glucose used, and the relative amount of the pure and impure article in the mixture, so the degree of impurity.

Given, then, a certain amount of arsenic in a certain glucose, used either alone or in combination with other

* Abstract from Report of Dr. Geo. Reid, County Medical Officer, Staffordshire, January 16th, 1901.

non-arsenical glucoses, the degree of contamination of the beer would be regulated, first, by the amount of glucose used, and, secondly, by the practice, when it is adopted, of mixing glucoses and the extent to which the mixing process is carried—in other words, the amount of arsenical dilution effected by the mixing.

PROBABLE EXPLANATION.

In view of what I have just stated, the comparative absence of arsenical poisoning cases in the populous towns in the north of the county is explained, for, although a large number of the public-houses in these towns were supplied with arsenical beer, it so happens that the implicated brewers not only used a moderate amount of glucose, but also lessened the arsenical quality of what they did use by brewing with mixed glucoses; thus in the case of one large brewery the arsenical glucose was diluted to the extent of two-thirds, and in two other cases to the extent of one-half. If in place of using mixed glucose, the three brewers referred to had used Bostock's glucose only, the quantity of arsenical glucose per gallon of beer would have amounted to 4·5 oz., 5·3 oz., and 5·6 oz. respectively, in place of 2·2 oz., 2·6 oz., and 1·8 oz., the amounts actually used.

USE OF ARSENICAL GLUCOSE NOT EXPLAINED BY MOTIVES OF ECONOMY.

It is popularly supposed that in using the special make of glucose which has led to such disastrous consequences, the brewers were influenced by economical motives, and it is but fair to them to point out that this was not the case. I believe the price paid for glucose varies from £12 to £9 10s. per ton, and the price actually paid for the glucose which was found to be arsenical was £11 10s. Both English and American glucoses are used, and it is only the latter which can be purchased at the cheapest rate. I found that one of the implicated brewers did use some American glucose, for which he paid £2 per ton less than that which he obtained from Bostock's. Believing the former to be inferior in quality to the latter, he only used it for brewing his low-priced beers, using the more expensive, and, as it turns out, arsenical glucose for his best beers. In another case, a brewer, in order to ascertain which make of glucose would be likely to prove most satisfactory, having regard to the character of the water used in brewing, &c., specially consulted a brewer's chemist on the subject, and it was upon his advice that he decided, in the first instance, to use Bostock's glucose.

WHO IS TO BLAME?

Having regard to the County Analyst's remarks upon the chemical aspect of the question, the Committee will probably be of opinion that either the glucose or the sulphuric acid manufacturer, or both of them, must, to say the least of it, have been guilty of the grossest carelessness. The glucose manufacturer must have known, or should have known, that there are two qualities of sulphuric acid in the market, and that the impure quality is likely to contain arsenic. This being the case, it is but reasonable to suppose that in ordering the acid he would have specified the quality he required, and, considering the purpose for which it was intended, one cannot conceive it possible that he would have ordered the inferior quality. Further than this, knowing, as he should have known, the serious risk involved, it would not have been unreasonable to have expected him to satisfy himself regarding the purity of each batch of acid supplied by having an analysis of it made upon delivery. On the other hand, as regards the manufacturer of the acid, supposing that the order specified the pure quality, in supplying the impure acid either a serious fraud was perpetrated or some one must have been guilty of the grossest carelessness. But even supposing that the quality required was not specified in the order, and the acid manufacturer had been in the habit of supplying Messrs. Bostock and Co., it is hardly conceivable that he could have been ignorant of the purpose for which the acid was intended, and, that being the case, he might at least have made inquiry as to which quality was wanted before executing the order.

In concluding this report I venture to predict that when, in accordance with the policy of the Committee, further samples of beer will shortly be collected for analysis, the new brews will be found to be free from arsenic.

REFUSE DISPOSAL IN THE TWENTIETH CENTURY.

The disposal of refuse in the twentieth century forms the subject of an admirable article written by Mr. G. Watson, A.M.I.C.E., M.I.M.E., which appears in a recent issue of the *Electrical Review*. In view of the interest which our readers take in this important question, we feel sure our contemporary will pardon us for reproducing the greater portion of the article in our columns. After a brief introduction Mr. Watson goes on to say:—

A refuse destructor properly designed and constructed is at present the only known means of disposal which satisfies both sanitary and economical requirements. Like most other improvements, it has been a long time on the way, but certainly the years from 1875, when such furnaces first began to be used, to the present time have not been wasted. They can now be made to work with perfect satisfaction in crowded neighbourhoods, completely surrounded by dwelling-houses, and they can be adapted for use on a large scale in big towns and cities, or on a small scale for villages, hospitals, and even hotels. They satisfy sanitary requirements by reducing town refuse to a hard innocuous clinker, with a proportion of ashes, without emitting from the chimney shaft any nuisance in the shape of stink, smoke, or dust. The stink and smoke are cured by maintaining the temperature within the furnaces themselves at from 1500 deg. to 2000 deg. Fah. The fine dust which used to be distributed from the chimneys of destructors working under strong natural draught was frequently mistaken for smoke, and there can be no doubt that it caused considerable nuisance. The early efforts to reduce it generally took the form of the provision of flues slightly enlarged, and provided with baffle walls, upon which the dust was supposed to strike, and so settle on the bottom of the flue. More logical designs were based upon the principle of making the flues very large, so that the velocity of the gases might be insufficient to carry the dust along, which was thus supposed to be deposited on the bottom of the flues. This arrangement was, of course, fatal to any chance of properly utilising the heat of combustion, owing to the expansion and cooling of the gases in these huge flues.

The stinks, which were undoubtedly caused by the working of early destructors, were due mainly to the use of natural draught, which drew such huge quantities of cold air through the furnaces every time they were either charged or clinkered as to keep them constantly at a low temperature. The stinks were to a great extent destroyed by means of Mr. Jones' "fume cremator," whenever that appliance was worked regularly with an abundance of fuel. This fume cremator consisted of a grate, with suitable rings of fire-brick above it, placed in the main flue between the furnaces and the boilers—when there were any. The cost of working was, however, so high that in most cases the cremator was only worked intermittently, or allowed to go entirely out of use, so that the full benefit of

it was seldom realised. The only types of destructor which may be said to prevail at the present time are designed to work at a high temperature under artificial draught, forced either by means of steam jets or fans, and in the furnaces with which the author is particularly connected the further precaution is taken that all the gases arising from the refuse drying, when it is first put into the furnaces, have to pass over the hottest part of the fire before they can escape to the chimney, while the products of combustion of all the furnaces in a battery are well mixed in a moderate-sized main flue (in which the brickwork is constantly at a glowing red heat) before they are passed into contact with the heating surfaces of the boilers.

To catch the dust the author has devised a large circular swirling chamber, in which the dust is separated by centrifugal force, in much the same way as cream is separated from milk in a centrifugal cream separator. Thus the escape of fine dust from the chimney is prevented. Destructors now satisfy economical conditions by the saving of cartage, the saving of labour, and the full use of the residuals. As regards the saving of cartage, this is effected by placing the destructors in the centre of the population area, and this course is now fearlessly advocated in all cases. The size of installation to be adopted depends, of course, largely upon the manner in which the heat is to be utilised, as well as upon the question of cartage; but it is noteworthy that the city of Hamburg is now destroying half of its refuse, amounting to about 250 tons a day, in the largest destructor in the world, consisting of 36 cells in one house. No doubt such a complete concentration involves extra cartage, but it saves expense in management and contributes to efficiency.

Saving of labour is probably the most important question in connection with destructors at the present time. The amount of labour required at different destructors varies in a most astonishing way. It is certain, however, that it ought not to exceed 7d. for every cubic yard of refuse destroyed in any district in the United Kingdom, and that where it does exceed that figure something is wrong. Seeing that, unfortunately, the cost of burning is usually stated in tons, irrespective of the number of cubic yards that go to a ton, and also of the percentage of moisture contained, it may be well to state that the refuse of London measures about two cubic yards to the ton, whereas in the North of England the muck does not exceed 1½ cubic yards to the ton.

The Strand Board of Works (now incorporated in the City of Westminster) has recently installed a large destructor, in which the refuse is tipped directly out of the collecting carts into the furnaces. The results of this arrangement have yet to be fully ascertained, but it is hoped that some pence per ton will be saved in the cost of feeding the furnaces, and a great sanitary improvement effected by making unnecessary the handling of the muck.

The use of the residuals is not less important than the saving of labour and cartage, and the twentieth century will utilise all its clinker for making mortar, concrete foot paths, fire-proof floors of concrete, concrete bricks and tiles. It will use all the fine dust caught in the dust-catchers as a basis for disinfecting powder, and all the ashes from the ashpits for plastering work. It will pass all its soldered cans through special furnaces in order to recover the solder, and to clean the thin steel plate from its coating of tin, in order that it may be used as scrap steel in steel works, and also in certain chemical manufactures. Most important of all, it will utilise in full the heat made by the combustion of the refuse, for raising steam, to be converted into light and power.

In the case of large destructors for big towns the power will generally be utilised in combined power plants for electric lighting, electric tramways, and electric power distribution; and in small villages the heat will be used to generate steam for driving stone breakers, chaff cutters, fans for smiths' forges, and other such tackle as is generally to be found in a town yard; and, in addition, for grinding mortar from the clinker, treating the clinker in breaking and sizing machinery for concrete purposes, and also in some cases for driving flag presses for making paving slabs, and brick machines for making bricks.

The Corporation of Bradford, the municipality of Hamburg, and the Vestry of St. Luke's, London (now part of the metropolitan borough of Clerkenwell), have probably up to now made the greatest advance in the matter of utilising the clinker. In all three of these cases the whole of the clinker is utilised for the above-mentioned purposes. In the case of St. Luke's very large orders for clinker have been received for the purpose of making concrete floors in warehouses. In Bradford a very brisk sale of mortar takes place, and also of broken and sized clinker for concrete purposes, and of ashes for plastering. Concrete paving slabs are also manufactured on a large scale. In Hamburg the clinker is used mainly for concrete purposes, and that it is appreciated is shown by the fact that no less than 125 tons of clinker are sold, or used by the town itself per diem. It may be remarked that the refuse of Hamburg contains 50 per cent. of incombustible matter. When the author was at the works about the middle of December last, there was not a cart load of clinker remaining on the premises, and it was being fetched away as fast as it could be produced.

Another very important question bearing on the economical result is that of the life of the furnace. The bill for repairs and renewals of a destructor may easily mount up to a most disastrous figure unless it be constructed in the first instance with the most suitable materials, and with all the skill and care which experience alone can furnish. The capital outlay to satisfy such requirements is large, but not so large as that required to rebuild the furnaces at frequent intervals. The day of cheap destructors is past. They must now be constructed so that the furnaces can be worked day and night, with the minimum of interruption for repairs for at least five years. Some engineers are advocating stand-by plants, requiring double the space and double the capital outlay that ought to be necessary. Such expedients are quite needless, in the author's opinion, if the furnaces are built according to the best modern practice; but the question of the life of the furnace will always remain one of the very first importance.

The most important by-product of the destructor—that is, the waste heat—yet remains to be discussed. Probably no question has been much more hotly debated than this. On the one hand, we have figures put forward by persons (of whom the author himself may be considered a type) too much interested to escape the suspicion of some people that he is too sanguine as to results. On the other hand, we have "cold water" poured in gallons by persons who are *not* sufficiently interested in the question to ascertain the facts.

This is not a subject which can be dealt with in general terms, and it would be just as unreasonable to say that, universally, you can obtain so many pounds of steam at a given pressure for so much refuse burned, as to say that you could get so many pounds of steam per pound of coal without stating whether the coal is "Best Welsh" or cheapest "Smudge." The fact is that town refuse varies far more in different towns than does coal in different collieries. It will, however, be safe to generalise to this extent, that in all districts in the neighbourhood of coalfields, from 1 lb. to 1¼ lb. of steam may be counted upon as available for external use for every pound of refuse burned in an efficient destructor, and that in residential districts, remote from

cheap coal, from ¾ lb. to 1 lb. of steam may be counted upon with equal certainty.

These generalisations are sufficiently correct for preliminary purposes, but it will be well for any engineer who has to give reports to study the question particularly upon the spot. The author knows of a seaside town which subsists upon summer visitors, where from the beginning of May to the end of September hardly a ton of coal is burned in domestic grates, gas fires being almost universal for cooking and warming. In the same town small gardens abound, and they contribute to the destructor an enormous quantity of vegetable refuse, which requires a lot of work to put it into the furnaces, and fills a lot of space when it gets there, contributing very little to the resultant heat. There are in the town in question very large numbers of combined privies and ashpits from which wet nightsoil, amounting to about 40 per cent. of the total refuse, is collected. It can, therefore, be readily imagined that the working of the destructor in summer, to give complete satisfaction to all concerned, is no easy matter, without having any regard to steam-raising. In the winter, on the other hand, the refuse contains large quantities of cinders, the garden refuse is largely absent, and the results are proportionately better. In view of such instances as this, it seems hardly necessary to warn electrical engineers and others against any person who comes to them with a general guarantee of so many pounds of steam per pound of refuse, before the guarantor even knows in what district the apparatus is to be installed. It is a fact worthy of note that efficiency is generally in inverse proportion to the size of the guarantee. After making the necessary reservations, it may safely be prophesied that the twentieth century will see destructors and power plants combined in almost every instance where the number of destructor cells exceed four. The destructor will cease to be regarded as an undesirable neighbour or a poor relation, and will be looked upon in its true light as a means of improving the balance-sheet of the power plant. In support of this, readers may be referred to what has been accomplished in the way of steam-raising at Oldham, Shoreditch, Darwen, Hereford, Bradford, Norwich, Fulham, and Beckenham, and many other towns where up-to-date combined plants are either in course of construction or commencing to work with the most promising results. The period of doubt and exaggeration, of controversy and failure, of absurd guarantees and poor performances, is passed; and refuse destructors have now entered the period of sober, useful performance. No one desires more than the author that the results should be recorded with strict accuracy and published with despatch and regularity, as fully and as fairly as the accounts of the electric light undertakings throughout the country. When this is done the twentieth century will be in a position to know what is the lowest cost at which it can be rid of its town refuse, after allowing fully for the value of the residual products, of which steam power will prove to be by far the most important.

Registration of Plumbers.—On Wednesday, the 23rd inst., a deputation of members of the Parliamentary Committee of the Irish Trades Congress waited upon the Right Honourable George Wyndham, Chief Secretary for Ireland, in Dublin, to urge his support of the aims of the Congress, including the Registration of Plumbers under statutory powers. In the course of a sympathetic reply, Mr. Wyndham expressed his sense of the importance of plumbers' work, and his opinion that a number of deaths and a great deal of disease were attributable to defective sanitation and to bad work by incompetent plumbers.

Local Government Board Reports.

The Sanitary Administration of Farnworth and Kearsley Urban Districts.

A heavy infantile death-rate, with inadequate explanations of the same by the local Medical Officers of Health, caused the Local Government Board to send down Dr. W. W. E. Fletcher to these places last March to inquire into the condition of sanitary affairs. His report has just been published. Dr. Fletcher describes in detail the sanitary administration of the Farnworth and Kearsley Urban Districts, which comprise the sub-registration district, and in both cases draws attention to several matters where he considers arrangements made by the Local Authorities to be unsatisfactory. The report also includes returns of the number of deaths from enteric fever of persons belonging to the sub-district from 1896 to 1899, and the number of notified cases of enteric fever in the two urban districts for the same period. In the Farnworth urban district it appears that enteric fever has each year since shown excessive endemic prevalence, although in none of these years has the incidence attained unmistakeable epidemic proportions. Even in 1899, when the attack-rate was greatest, there was sustained prevalence of the disease throughout the year rather than any pronounced epidemic. The large proportions of enteric fever patients who were removed to hospital is noteworthy, and Dr. Fletcher considers it aided in preventing the disease from assuming epidemic proportions.

After detailing the observations made during his visit, and making several comments on the administrative work of the districts, Dr. Fletcher, concludes:—

There has been heavy mortality from diarrhœa in the Farnworth registration sub-district during 1899, especially in the third quarter, when 72 deaths occurred, the deaths in the corresponding quarters of the three preceding years having numbered, in chronological order, 26, 60, and 58. The mortality of infants under one year per 1000 births in Farnworth urban district for 1899 amounted to 259, as against 163 for England and Wales for the same period. In Kearsley urban district it amounted to 186. It may be stated that, owing to mothers working at mills, many young children are put out to nurse during the day; consequently they are likely to be less well cared for than they would be if nursed and fed by their mothers. There is, too, the possibility of soothing syrups, &c., containing opium or other dangerous drugs, being administered to keep the children quiet; and there is, perhaps, also the additional risk of exposure of tender infants to the early morning air, and again to the night air when being taken to and from their day-nurses' residences by the mothers. Much of this heavy mortality was due to infantile diarrhœa, which is especially apt to prevail during the autumnal months. Heavy "infantile mortality" rates are generally associated with districts in which the women go out to work, and in which, consequently, young children are put out daily to nurse. This practice is far more prevalent in Farnworth than in Kearsley, and the difference in the rates for the two districts is very marked. Autumnal diarrhœa, as is well known, must be in large measure determined by improper feeding of infants. Thus not only are feeding bottles and their tubes apt to be imperfectly cleansed, if not actually neglected, but the milk may, on occasions, be of poor quality, or too much diluted, or even sour; almost

invariably it is unboiled. Very frequently, if not usually, starchy food such as bread, biscuits, &c., which are indigestible by young infants, are administered. By such improper feeding the infant is predisposed to attack by "zymotic diarrhœa;" or, as a direct result of improper food, stomachic and intestinal irritation is set up, frequently followed by acute gastritis and enteritis, characterised by sickness and diarrhœa, and death often ensues. Causes of diarrhœa, such as these, are rendered more active in hot weather, since this is more favourable to development and activity of the specific organism of diarrhœa, and also to rapid changes in food-stuffs, especially milk, which are liable to decomposition. But there are also other causes which exert a powerful influence on the prevalence of autumnal diarrhœa, and greatly encourage its local incidence and persistence. Chief among these are unwholesome circumstances, and especially such as are associated with pollution of the air and soil by decomposing animal and vegetable substances, and, among such, the foremost rank must be given to excremental material. These unwholesome conditions, moreover, are precisely those which encourage also the development, prevalence, and persistency of enteric fever. They have been shown to exist extensively throughout both the districts under consideration, and have undoubtedly had a large share in inducing diarrhœa, and in developing from infected material outbreaks of enteric fever, and in fostering the disease in an endemic form in the locality. If the District Councils continue to permit the existing unwholesome conditions, the districts will probably suffer a penalty similar to those experienced in other places where like conditions have not been removed; the endemic disease may assume epidemic proportions with a correspondingly enhanced mortality. A serious responsibility rests upon these Councils, and they should see to it that they do not become answerable, collectively as Councils, and individually as Councillors entrusted with the care of the health of the inhabitants of their districts, for a prolongation of the unsatisfactory state of things now existing, with its concurrent risks and possibilities.

MR. COSHAM'S SEWAGE SYSTEM.

SUCCESSES IN THE DURHAM DISTRICT.

Last week several members of the Brandon District Council, Durham, met at the recently-erected sewerage tanks at Langley Moor, when the sewage was turned into the tanks for the first time for treatment. Mr. Cosham, the patentee of the precipitating tanks in question, was in attendance to explain the working of the same. After spending some time in the examination of the works in detail, the company adjourned to the Langley Grand Hotel at the invitation of Mr. Cosham, where an excellent repast was partaken of.

The Chairman said it afforded him great pleasure to meet Mr. Cosham, the members of the Council, and other gentlemen, on the completion of the tanks for the disposal of the sewage of Langley Moor. He trusted that the tanks would come up to the expectations that were formed of them. They already had two or three in different parts of the township, and might perhaps require more. He was glad that Mr. Cosham was present on the occasion to enlighten them on the system of sewage disposal which he had patented. With these few remarks he proposed "Success to the sewerage tanks."

Mr. Cosham said it afforded him very great pleasure to meet the members of the Council and other gentlemen on that occasion. Had this been the first tank that had been erected the members might have felt a little diffident as to whether they were going to be a success or not, but as this was the third installation the Council had put down they might be expected to know something about the system. He would endeavour to enlighten them as to the value of these tanks. Mr. Gregson, of Durham, was the first gentleman to introduce the system to this neighbourhood, having witnessed the installation at Nuneaton, where about 500,000 gallons of sewage were disposed of daily. Now systems for the disposal of sewage were about as numerous as quack pills, much advertised, and each professing to be the only satisfactory system in existence. It was very hard work, then, to get any Authority to adopt his system, but at last he was successful at Nuneaton, and so satisfactorily did the system work there that other Authorities gradually adopted them. Mr. Snowdon, the surveyor to the Sedgefield District Council, wrote him a very flattering testimonial to the effect that the tanks gave most satisfactory results, so much so that his Authority had decided to deal with other places in the district by the same method. The system of sewage treatment consists in precipitating the solids by chemicals. The sewage on reaching the outfall works passes through a screening chamber, so constructed as to thoroughly break up the solid matters and reduce them to a state of suspension fit for subsequent treatment and removal. It then flows through the chemical cage, constructed so as to accurately regulate the quantity of cake consumed to the flow of sewage. The sewage is then conveyed by a pipe discharging into the central portion of the tank, and after passing through a series of divisional chambers, is finally taken to the natural filtration beds or land. The sludge is extracted automatically, and finds its way by gravitation into sludge beds. The chemical used was alumino-ferric, the expenditure on which was very small indeed. In conclusion, he maintained that by adopting his system a very great saving would accrue to the ratepayers. He had put fifty different installations of his system down in various parts of the country, and had not had a complaint yet. He suggested that the Surveyor and Medical Officer should experiment upon the tanks for a short time, using one to be treated by the bacterial process, and the other by precipitating the sewage by chemicals, and they would soon be convinced that the latter was by far the better method of treatment. In conclusion, he considered that the District Council were justly entitled to the admiration of the ratepayers of the district for introducing a system which had proved in other places to work with both efficiency and economy.

On the motion of Mr. Barnes, seconded by Mr. Pearson, a cordial vote of thanks was accorded to Mr. Cosham for his interesting and instructive address.

The town of Langley Moor is of about 4000 inhabitants. The works consist of two circular tanks, the cost of which, including charges for patent rights and fittings, only amounted to the sum of £500. This works out at the cost of only 2s. 6d. per head of the population. The labour required on the works will be one labourer one day per week, and the cost of chemicals will not exceed 5s. per week. The £500 does not, of course, include the cost of sewers and land.

Small-pox continues to increase in Glasgow rather alarmingly. Up to Wednesday in last week, the total under treatment — excluding dismissals—was 202. Fortunately the disease continues to be of a mild type. Considerable reluctance to be re-vaccinated has been shown, even by the inmates of houses where the disease has broken out, but a more intelligent feeling is beginning to evidence itself. Arrangements are being made to establish a number of re-vaccinating stations in the city.

HEREDITY AS A FACTOR IN THE CAUSATION OF TUBERCULOSIS.

In recent years there has been a marked change in the opinion of medical men in regard to heredity as a factor in the causation of tuberculosis. Speaking from the present point of view, says the *Sanitary Inspector* (official bulletin of the State Board of Health, Maine, U.S.A.), we may say that pre-natal infection is rare, and that true heredity almost never occurs. The truth of this is indicated by the present position of most of the leading medical authors and teachers; by the results of recent statistical studies of tuberculosis, in which the errors in the earlier studies have been eliminated; by the records in the hospitals for children and in foundling and orphan asylums; by the studies in pathological institutes; by observations among animals artificially infected; and by the observation of the veterinarians.

Cornet, making a careful study of the whole tuberculosis mortality of Prussia covering a period of sixteen years, shows that the mortality curve is higher during the first year of life than at any time until the twentieth year is past. The high death-rate during the first year of life, according to this eminent authority on tuberculosis, is not an indication of heredity, but is due to the more intimate association with tuberculous mothers during the first year and the rapid prolification of tubercular lesions which follows infection in the earlier weeks or months of infancy.

The observations of Heubner in his Berlin clinic confirm those of Cornet, but he shows that during the first three months of life tuberculosis is a rarity, to say the least. In his clinic during the last five years, as he stated last year, there were :—

Children.	Ages.	Tuberculous. Per cent.
844	3 months or under	None.
218	3-6 months	3·6
93	6-9 ,,	11·8
75	9-12 ,,	26·6
458	second year	14·2
367	third ,,	13·4
306	fourth ,,	11·1
470	fifth-sixth ,,	7·4
682	seventh-tenth ,,	5·0

Thus with Cornet he finds a large prevalence of tuberculosis during the first year, but he found no tuberculous children during the first three months of life. In experiments upon animals, says Heubner, we know that the time which elapses after the inoculation of the bacillus of tuberculosis before gross pathologic changes of the internal glands take place is from two to three months. Now, new-born children in general remain free from visible signs of tuberculosis just these three months. No more striking proof could be presented that the tuberculosis of young children is acquired, and not brought with them into their post-natal life.

The experience of Boltz is like that of Heubner; no cases of tuberculosis under the fourth month. In the Berlin Pathological Institute this rich field of observation disclosed no case of tuberculosis in children under two months, and only two under three months of age, and Dr. Virchow, the eminent director of the Institute, declares :—"I deny emphatically the heredity of tuberculosis."

We may say that in the absence of chances of infection after birth tuberculosis rarely occurs. The truth of this is attested by many observations in medical circles. Those of Bernheim of Paris are interesting, particularly his three histories of twins born while the mothers were tuberculous.

"In each instance one of the children was reared in its own home, being nourished by a healthy wet-nurse, while the other child was sent from its home and reared in the country. The three children which remained at home died; one of consumption, the two others from tuberculous meningitis. Two of the nurses also died of tuberculosis. On the other hand, the three children which were removed from their homes and reared in the country under healthful hygienic conditions are all still living and well."

The experience of the veterinarians in Denmark in recent years in separating calves from their tuberculous dams is equally convincing that the influence of heredity has been very greatly overrated.

Sanitary Inspectors' Associations.

South Wales and Monmouthshire.

The fourth annual meeting of the Association was held at the District Council offices, Aberdare, on Saturday, the 26th of January, 1901.

A Council meeting was held in the forenoon, Mr. D. Vaughan and Mr. J. Preece James, the newly-elected chairmen, presiding. Mr. J. Preece James (Tenby) was elected chairman for the ensuing year, and Mr. John T. Owen (Merthyr) and Mr. James P. Jones (Gelligaer) vice-chairmen; Mr. W. Lloyd-Marks (Rhymney) was elected treasurer.

Subsequently the annual meeting was held, presided over by the president of the Association, Dr. W. Williams, Medical Officer of Health, Glamorgan County Council. There were also present: Dr. W. Ll. Rhys, Deputy Medical Officer of Health, Aberdare; Colonel Thomas Phillips, solicitor, Clerk to the Aberdare Urban District Council; Messrs. D. Vaughan; J. Preece James; James P. Jones; John T. Owen; W. Williams; T. W. Warren; Spencer E. Jones; and the hon. secretary, Mr. J. Towy-Thomas, together with representatives from Aberdare, Merthyr, Hengoed, Cefn, Tenby, Cardiff, Swansea, Blaina, Monmouth, Rhondda, Newport, Gowerton, Barry, Ferndale, Pentre, Tonypandy, Treherbert, &c. &c. The following gentlemen were elected to honorary membership :—Dr. C. E. G. Simons, M.O.H. (Merthyr), Dr. J. Pugh Jones (Ynyshir), Mr. W. D. Morgan (Architect and Surveyor, Pentre). Messrs. Thomas Bowen (Pontypridd), S. John James (Login), R. J. Davies (Hengoed), D. J. Jones (Pontypridd), J. W. Jones (Swansea), and David B. Phillips (Cardigan) were elected members.

The Hon. Secretary presented the Council's annual report, which showed steady progress and a vigorous determination to push forward the cause of the Sanitary Inspector. It was adopted with acclamation.

The Treasurer presented his statement of accounts, which showed a substantial profit on the working of the year.

Mr. W. J. Hopkins, Chief Port Sanitary Inspector, Barry, was re-elected librarian; Mr. J. P. Jones and Mr. T. W. Warren were re-elected auditors; and Mr. George Thomas and Mr. W. Williams elected scrutineers.

Mr. Samuel James, C.S.I., Chief Sanitary Inspector, Aberdare, read a most instructive and practical paper on "House-to-house Inspection," which evoked considerable discussion.

At the close of the meeting the members adjourned to the Boot Hotel, where they were entertained to luncheon by Colonel Thomas Phillips, who was enthusiastically thanked for this unexpected appreciation he had bestowed upon the members.

Notwithstanding the inclemency of the weather, the meeting was a grand success.

National Health Society.

OFFICIAL TRANSACTIONS.

Training courses for the Sanitary Inspectors' Examination Board Certificate and for the Diploma of the National Health Society.—Syllabus of lectures and demonstrations on "Public and Private Hygiene," by John Gay, M.R.C.S., L.R.C.P., D.P.H. Tuesdays and Fridays, at 3.30 p.m., at 53, Berners-street.

LECTURE I.—Air. Composition of Atmosphere—Atmospheric Conditions affecting Health—Meteorological Observations—Sources of Vitiation of the Atmosphere.

,, II.—Air (continued). Effect of Vitiated Air on Health—Overcrowding—Back-to-back Houses—Natural and Artificial Means of Ventilation—Warming—Lighting.

,, III.—Water. Sources of Water—Drinking Water—Sources of Pollution of Drinking Water—Methods of Prevention.

,, IV.—Water. Collection, Distribution, and Storage—Constant and Intermittent Supplies—Lead in Drinking Water—Hard and Soft Water—Water-borne Disease—Filtration and Filters.

,, V.—The Habitation. Characters of Various Soils—Pollution of Soils—Ground Air and Subsoil Water, their Effects on Health—Aspect, Site, Foundations, Walls—Damp, Cause and Prevention, Effect on Health — Dwelling-houses, Schools, Hospitals.

,, VI.—House Drainage. Drainage in Town and Country — Water Carriage System — Faulty and Correct Arrangement of Drainage—Traps—Joints—Fall—Disconnection—Ventilation of Drains—Testing.

,, VII.—Demonstration at the Parkes Museum.

,, VIII.—House Drainage. Conservancy System—Cesspools — Middens — Privies — Pail Systems — Dry-earth System — Sewage Disposal — House Refuse, Collection and Removal — Refuse Destruction — Scavenging.

,, IX.—Demonstration.

,, X.—Demonstration.

,, XI.—The Calculation of Areas and Cubic Space.

,, XII.—Demonstration.

,, XIII.—The Laws of Health. The Functions of the Body—Cleanliness and Filth—Filth and Disease—The Hygiene of the Skin—Clothing—Bedding—Hygiene of Different Periods of Life—Infancy, Childhood, Age—Exercise.

,, XIV.—Diet. Classification of Foodstuffs—Values of Foods—Preserved Foods—Diet for Work, for Sustenance, and for Disease—Diet for Infants—Vegetarianism—Beverages—Alcohol.

Demonstrations at the Parkes Museum and of sanitary and insanitary areas, &c., will be notified during the course of the lectures, which will be detailed and fully illustrated by models, diagrams, and experiments.

THE first lecture on "Nursing" was given on Thursday last, and the course will be continued on the five following Thursdays.

ON Monday (January 28th), Dr. Cantlie gave his first lecture on "First Aid." The lecture was well attended, but there are still vacancies for more ladies in the class.

THERE are still a number of copies of the N.H.S. almanacks for 1901 to be obtained, and these will be sent to the Society's lecturers for free distribution amongst their classes, on application to the Secretary at the office, 53, Berners-street.

PRESENTATION.

ON Thursday evening, January 24th, 1901, at the Council offices, Pentre, Rhondda, Dr. Herbert Jones, Medical Officer of Health, and Mrs. Jones, were the recipients of valuable presents upon their leaving the district for Hereford, where Dr. Jones has been appointed to a more lucrative appointment.

Mr. W. J. Jones, Engineer and Surveyor to the Rhondda Council, presided, and was supported by Councillor M. Morris, J.P., Chairman of the Rhondda Council; Alderman Walter H. Morgan, Clerk; Dr. T. W. Parry, Dr. W. E. Thomas, Dr. E. N. Davies, Dr. Ivor H. Davies, Dr. T. H. Morris, Mr. James Miles, National Collieries; Mr. Evan Llewellyn, Mr. Octavius Thomas, &c.

Dr. Herbert Jones was presented with an old oak pedestal desk, exquisitely carved, with nest of drawers, and chair to match. The presentation was made by Councillor M. Morris. Mrs. Walter H. Morgan made a presentation to Mrs. Herbert Jones of a silver tea service and tray. Dr. T. N. Parry made a joint presentation to Dr. and Mrs. Herbert Jones of a beautiful case of knives and forks, spoons, &c. Mr. J. Towy-Thomas, Chief Sanitary Inspector, Rhondda, on behalf of himself and colleagues, presented Dr. Jones with a fine photo group of the Rhondda Sanitary Staff, Dr. Herbert Jones being the central figure.

In addition to the above speakers who made the presentation, speeches were delivered by Alderman Walter H. Morgan, Mr. James Miles, and Dr. T. H. Morris, C.C. Light refreshments were supplied, and a most enjoyable evening was spent. Dr. Herbert Jones takes with him the good wishes of the thousands in the teeming Rhonddas. This is much to say when we take into consideration that the Rhondda Council is the largest Urban District in the United Kingdom.

The appropriate lines read by Mr. Towy-Thomas verily touched the audience; his closing lines were:—

> The words unsaid, the things undone,
> Must go, we say farewell;
> Prosperity roll on, roll on,
> The mutual tale to tell.

CORRESPONDENCE.

(We do not in any way hold ourselves responsible for opinions expressed by our correspondents.)

(To the Editor of THE SANITARY RECORD.)

BOER BULLETS—ARE THEY POISONED?

SIR,—I have recently examined some bullets which were supposed to be poisoned, and I found that they were coated with paraffin wax, tinted a pale green with a salt of copper. There was no other poison present, organic or inorganic. It cannot in any practical sense be called a poisoned bullet. The bullets were genuine, and were picked up on Harts Hill after the battle of Colenso. They have the appearance of having been dipped into a bath of melted paraffin which had become green from frequent contact with the edge of the copper cartridges. The copper may, however, have been purposely added in order that the Boer rifleman should believe he had a more than ordinarily deadly weapon in his hand.

—Yours faithfully, ARTHUR ANGELL,
Southampton. *Public Analyst.*
January 17th.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

THE HOSPITALS COMMISSION REPORT.

THE Report of the South African Hospitals Commission, which was issued last week, is in its general tenor much what we had been led to expect, and may be considered by the public to be eminently satisfactory. The fears that have been entertained by some persons that it would not be thoroughly impartial, or that it would whitewash the authorities, may be at once discarded. There is not a vestige of such a thing in the Report. Praise and blame are dispensed with even-handed impartiality, where they are deemed to be due—and it is satisfactory to know that the praise predominates. So far as organisation was concerned, the Commissioners, it is true, point out many defects, some of them due to the same causes as have contributed to the difficulties and protractedness of the war as a whole, others to the ordinary constitution of the Royal Army Medical Corps. The heads of the Army Medical Department no more foresaw the magnitude or duration of the war, and the vast difficulties that would have to be contended with, than did the general military authorities; and for that it is difficult to blame them, for the whole nation was taken by surprise. It is fair to say that these things could hardly have been foreseen. But the Commissioners are at pains to point out that even had the difficulties been foreseen, the Army Medical Corps would have been unprepared, and from its constitution was ill-fitted to meet them. They state that not only was it wholly insufficient in staff and equipment for such a war, but "it was not so constituted as to have means provided by which its staff could be very materially enlarged or its deficiencies promptly made good." For that they hold that the Director-General and his staff cannot be blamed, for "they had for a considerable time before the outbreak urged upon the military authorities for an increase of the corps, but for the most part without avail." The War-office is thus put upon its defence, and their responsibility in this connection will no doubt be debated in Parliament. The reorganisation of the Army Medical Department, so as to render it capable of meeting any possible demand in the future, must form part of the whole scheme of Army Reform, which is to engage the attention of the Parliament about to meet. The public can now realise not only the urgency, but also the magnitude of the reform that is necessary. But it is satisfactory to us to learn that for any shortcomings the medical authorities cannot justly be held responsible. With regard to the mode in which the Medical Corps discharged their duties, the Commissioners remark that, like every large body, it has its unfit or bad members, but the proportion of bad members was very small, and speaking of the officers as a whole, their conduct and capacity deserved great praise.

There is a word of blame for the Surgeon-General in South Africa for having apparently failed to fill up the blanks left in consequence of the withdrawal of field hospitals from units already organised. But considering the whole situation, the enormous difficulties of transport and the like, and the military necessities of the campaign, the Commissioners consider that the principal Medical Officer and his head staff did excellent work, never sparing themselves, and showing every desire to provide for the comfort of the sick and wounded. All requisitions from South Africa were promptly met by the home authorities, and their efforts were ably supported by the authorities at the base in South Africa. Taking into account the inevitable difficulties, the Commissioners were well

satisfied with the way in which the railway authorities, both civil and military, discharged their duties in connection with the transport. And the hospitals they found at the time of this visit to be in excellent condition, and well supplied both with staff and equipment, and the sick and wounded were very well attended to. That disposes of the greater part of the fabric of charges raised by Mr. Burdett Coutts and his fellow alarmists. Still, the Report indicates that there are large fields in which improvement is necessary, and it contains many important suggestions for remedies, which will, no doubt, receive due consideration. But the concluding passage of the Report must be peculiarly gratifying to all who are sensitive about the national honour. "We desire to say that, in our judgment, reviewing the campaign as a whole, it has not been one where it can properly be said that the medical and hospital arrangements have broken down. There has been nothing in the nature of a scandal with regard to the care of the sick and wounded; no general or widespread neglect of the patients, or indifference to their suffering; and all witnesses of experience in other wars are practically unanimous in the view that, taking it all in all, in no campaign have the sick and wounded been so well looked after as they have been in this."

The Plumbers' Registration Movement.

Various meetings of the plumbing trade are at present being held in different centres, with a view to carrying out one of the most important resolutions adopted at the Birmingham Conference held on October 24th last, viz., that for the establishment of two grades of registration, one for operative plumbers and the other for master plumbers, Inspectors, and plumbers occupying similar positions; and also for recognising as eligible for registration in the operative grade all operative plumbers who have already passed the requisite examination in workmanship, or who may produce proof satisfactory to the Registration Committees of the respective districts that they have been earning the standard rate of wages in the districts in which they work. The facilities for registration for the class of operatives last mentioned are to be limited to those who apply not later than February 28th, 1901. At a meeting recently held in Glasgow, Dr. John C. McVail, Medical Officer of Health for Dumbartonshire, likened the present stage in the plumbers' registration movement to the one through which Medical Officers had passed. He pointed out that at first practitioners were appointed who had no special health diploma, then voluntary effort came in to provide such diplomas, and public Authorities came more and more to regard them as essential qualifications; and finally the possession of a public health diploma was made imperative by statute. And, as in the case of many men who were established in practice before the Medical Act was passed, and to whom, with wives and families dependent on them, it would have been a hardship to be deprived of the advantages of a registered qualification, entrance was given within a fixed time; so on the same principle, and in accordance with usage, an opportunity was now to be given to men who were known to be good practical plumbers to get upon the list. There can be little doubt that sooner or later the present voluntary system of registration will develop into one in which it will be imperative for a man to be registered in order to be recognised as a qualified plumber. In order to encourage operatives to take advantage of the present opportunity, it has been decided to reduce the entrance fee, and it is earnestly hoped that the trade will make a hearty response. The Plumbers' Registration Bill is to be vigorously prosecuted in the coming session of Parliament—with what prospect of a successful issue it would be unsafe to predict.

A Scottish Sanatorium.

Some interesting details are given by a correspondent in a Scottish paper of the new consumptive sanatorium just completed at Banchory, on the Middle Deeside. This is the first establishment in Scotland which has been specially designed and erected on a specially-selected locality for carrying out the Nordrach treatment. Erected at a cost of over £600 per bed, it is claimed for Nordrach on Dee that it is by far the finest of its kind in Britain, and one of the best in Europe. Great care was exercised in the choice of a site, months being spent in scientifically comparing the topographical and climatic conditions that obtain in many different areas. In the case of the German sanatoria, no effort is spared to procure the most desirable atmospheric surroundings, so much importance is attached to the quality of the atmosphere as a factor in the success of the treatment. Hence Middle Deeside has been chosen for its dry, bracing, ozone-laden atmosphere, and the mildness of its winters. The grounds extend to about 25 acres; and the lengths of the walks are graded according to the strength of the patient. Shelters are erected here and there among the trees, some of them being on the revolving principle. The outdoor attractions are to be increased by the provision of a winter garden in the verandah that connects the sanatorium with the dining-room. The sanatorium has accommodation for forty patients, and there are present thirty inmates.

A Compromise Needed.

A paragraph in the *Sussex Daily News* last week indicates one of those unfortunate cases where localities are let in for heavy costs through the exercise of a little obstinacy instead of a more compromising spirit on the part of those in power. According to our contemporary, the drainage proposals of Haywards Heath are still engaging the attention of the parishioners of Lindfield. The impression carried away from the recent inquiry by most impartial people was that the question should be settled by some sort of compromise, and a most conspicuous

feature of the evidence was the want of unity on the Lindfield side. They were unanimous in opposing the Haywards Heath scheme, but apparently were not agreed on an alternative. The Lindfield Parish Council have had a special meeting to consider the question, and have appointed a deputation to wait upon the landowners likely to be affected by the suggestion of Mr. W. Sturdy and his agent, Mr. Millard, that the sewage should be taken on to a site at Noble's farm, with a view to obtaining their favourable consideration. If at all successful, the Parish Council would then endeavour to prevail on the Committee of the Rural District Council to support the proposal and join with the parochial representatives in asking the Haywards Heath Council to accept the compromise. The feeling at Haywards Heath is undoubtedly friendly to Lindfield, and it is only owing to the conformation of the ground that it is proposed to take the sewage into Lindfield. If the Lindfield representatives and the owners concerned agree, and point to a site where Haywards Heath could go on fair terms and without opposition, both districts would be satisfied, and the problem solved without the aid of Parliament. It is quite clear that the Lindfield people have no real grievance, for all unbiassed people agree as to the utility of the Haywards Heath proposals. But there are some people who must object to everything. We do not mind that if they have to pay for their whims. What we object to is their burdening the ratepayer with costs that are wholly unnecessary in order to get their own way.

Hospital Reform.

Much thought and anxiety have been expended in recent years on the hospitals of the metropolis. But somehow or other things do not go quite so well as we should like. Some put the blame in one quarter, and some in another. There must be something wrong somewhere, or else we should not have those periodic spasms of complaint which find their way into the daily Press. It may be, as a writer points out in the *Morning Post*, that the officials are the weak point, and that the lack of courtesy by many of these individuals works against the institutions. At the close of an excellent article, the author says that we of the British race have been "commended for many excellences, but we have never been congratulated on a national courtesy. Doubtless an insular instinct leads us to raise obstacles and barriers in the way of all forms of new enterprise, but it is a national pity when obstacles are placed against a popular entrance into the hospital world. For it is a charming world, and the workers of our institutions are nearly all acting up to a high standard of charity and kindness to the sick under their care, so that they have no cause to shrink from criticism. There should be, and there often is, something very gracious and 'pitifully courteous' about the atmosphere of a hospital. And the officials of such an institution should be the first to copy nature's plan of covering up the dry bones of necessity with comely and attractive externals. From the mere commercial aspect of the case there would be fewer hospitals with the dread of debt hanging over them were the graceful working of the machinery displayed in an organised system of institutional amenities. I could cite one matron who contributes £500 yearly to her hospital from the voluntary offerings of interested visitors whom she takes round the wards. Popularise the hospitals and the public will gladly pay the bills. The routine work is admirably done. But it sets its light under a bushel, and the public often forgets to drop a contribution into the box because the box is kept in the shadow."

Bradford Refuse Disposal.

The thriving town of Bradford in Yorkshire is becoming quite celebrated for its successful municipal projects. Everybody is talking about the wonderful things it is doing, and papers are holding it up as the model of what a spirited municipal government can accomplish. The reason for much of the interest manifested in the work of the place may be traced back to the visit of the British Association last year, when so hearty a Yorkshire welcome was extended to hundreds of visitors from all parts of the United Kingdom. Doubtless the thing that impressed most people was the work accomplished under the direction of Mr. McTaggart, the superintendent of the Cleansing Department. Each week confirms the utility of the refuse disposal works. Our readers will remember that the Corporation clears all the ashpits at regular intervals, taking the refuse to the destructors, where it is passed through the fire, and the clinkers remaining are ground into powder, which in turn is placed into moulds, pressed, and thus producing paving flags ready for use. These have been thoroughly tested, and have proved equal to the best stone. By these and other means, Bradford has reduced the cost of its refuse destruction to less than one-half what is paid by the great majority of districts. No wonder that other Corporations and Councils are sending deputations to inquire "how it is done." It is simply this, that the officers were encouraged to make experiments, and that now the town is reaping the benefit of its enterprise.

Vigilance Committees.

Ratepayers' Associations and Vigilance Committees may be very useful or very harmful bodies. When they exist simply to attack individuals or make petty criticisms they are not of much service, and generally prove themselves to be the last persons to whom the interests of any community may be entrusted with safety. But if they are composed of sincere men they may do much good. Such a one was that which came into existence shortly after the plague had made its appearance in Sydney. The City Council did not appear to realise the enormity of the evil which had invaded its borders, hence many influential citizens banded themselves together to show the Council its duty. Lacking the executive power to carry out thoroughly the work which required to be done, it could only act as an agency

of investigation and supervision; but in this capacity it has rendered invaluable service to the public. The City Council professed to scorn the Vigilance Committee, but there is no doubt whatever that the repeated public exposures it suffered at the hands of the latter body spurred it into taking reluctant action on many occasions. How hard and earnestly the Committee worked is shown by their report. They received and dealt with 1862 complaints regarding 2178 premises which were alleged to be in a rat-infested or insanitary state, besides many hundreds of letters referring to matters within the scope of their activities. Three thousand six hundred and thirty visits of inspection had been made, and 6487 letters had been written to the various Authorities and to the public. How dilatory the responsible officials were is made apparent by some of the results given. "Of the 2178 premises complained of, the Committee received definite information that 1182 had been, or were being, attended to, while 31 were matters between landlord and tenant, with which the Committee could not interfere. Of the rest a few might have been put right since the Inspector's last visit, but the majority still required attention." With the expulsion of the plague some suggested the disbanding of the Committee, but this has not been done. It has simply "adjourned." And if the City Council fails to insist on the carrying out of much-needed reforms, the Vigilance Committee will spring forth once more to compel it to do its duty.

Storage of Petroleum.

Concerning a reply to a query which appeared in our "Notes and Queries" (No. 2051) a correspondent writes :—"I have for a long time been urging that the use of the word 'petroleum' in the Acts is misleading, because it gives one the impression that there are restrictions on the sale and storage of all petroleum, *i.e.*, mineral burning oils. As, of course, you are aware, the Acts only apply to petroleum which flashes at 73 deg. or under. Any oil which flashes at over 73 deg. may be stored and sold absolutely without restriction of any kind, excepting in the case of regulations made by a few local bodies as to hawking. Now, your answer is exactly correct, but I think that some readers might suppose that any petroleum oil would have to be kept divided up into bottles holding a pint or less, which, of course, is not the case. What I think ought to be done would be to call all petroleum under 73 deg. flash point petroleum spirit, and that above petroleum oils." We may add that we are thoroughly in accord with our esteemed correspondent in this matter.

Sandgate "Homes."

We continue to be favoured with correspondence relating to the management of the Jones "Homes" at Sandgate. Some of the letters are couched in terms the reverse of complimentary to Mr. Jones, but a general opinion prevails that the matter is of the utmost importance so far as the welfare of the town is concerned. It appears that there has been a further outbreak of typhoid in one of the houses, supplemented by scarlet fever in another. From a public health point of view it would be interesting to hear what the Medical Officer of Health has to say to the presence of typhoid in a house where there was typhoid last August, and whether this second appearance of the disease within five months of the first does not disturb his optimistic faith, expressed by him to the representative of a London daily paper, that "there is no fault to be found with any of these homes." We have no desire to enter into a controversy on the culinary arrangements of these places, concerning which there are also complaints, but we do think, for its own sake, the little town should stir up its Health Authority to investigate the source of these outbreaks of infectious disease. An isolated statement it can afford to ignore, but statements which bear upon them *primâ facie* evidence of trustworthiness can hardly be so treated. Nor can a journal which is devoted to public health matters pass them by without comment.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

I have been asked by a correspondent if I will state my opinion as to the propriety of an engineer or surveyor using the initial letters "C.E." after his name. I am not sure that anything which I can say will be helpful, as the matter is one which must be decided by a man's conscience and taste. It is alleged, I understand, that no person who is not an associate or member of the Institution of Civil Engineers is entitled to the use of such letters. Such an opinion comes, of course, from members of the Institution which has done so much to raise the status of engineers, and which wields such an influence over the profession. The opinion given under such circumstances must, however, be taken as *ex parte*, and naturally enough is not a disinterested one. The Institution of Civil Engineers is not, it should be remembered, the only association of engineers in the kingdom, and until quite recently persons were admitted to associate membership with scant qualifications and without undergoing any examination, and on this account many engineers, to my knowledge, refused to become members. Partly on this account, and also because the numerical strength had grown to such proportions and the finances of the Institution had become so great as to make it practically independent, and mainly because the instinct of self-preservation asserted itself so strongly, that a majority of the members who had safely entered its portals obtained a resolution to close the doors as far as possible to other candidates. The Institution now, with a few exceptions only, admits new members after passing a qualifying examination.

It, of course, follows that the number of new members yearly admitted will be greatly restricted. But the end aimed at has been secured, with much satisfaction. I would, however, point out that the Institution of Civil Engineers is not alone in imposing increased qualification for membership, for the Incorporated Association of Municipal and County Engineers have also imposed, quite recently, new restrictions, so as to prevent persons whose qualifications are doubtful from

becoming members. But it is an improper assumption to say, as it appears is done, that a person who is not a member of the Institution of Civil Engineers is not entitled to the use of the letters "C.E." Many engineers there are who have passed examinations as surveyors under bodies other than that of the Institution in question, and their qualifications are better than those of a large number of existing members who passed no examination whatever, and whose principal qualification was the payment of a substantial entrance fee. I do not, however, hold that any person is entitled to use the letters. He must possess some qualification, which may be evidenced by a considerable and long practice as an engineer and surveyor, or by a *testamur* that he has passed an examination for engineers or surveyors held by some association or body of repute. Under such conditions he is, I think, as much entitled to use the letters as a medical man who has only obtained the qualification "L.R.C.P." is to the term "doctor"—though, to be correct, no medical man is entitled to the appellation unless he has obtained the degree of "M.D."

I am not sure whether it is generally known that Local Authorities who wish to raise money for carrying out some improvement in their district without defraying the cost thereof out of current expenses or without going to the Local Government Board for their approval and sanction for a loan can do so with considerable ease, providing they are possessed of land purchased for the purposes of sewage disposal. I have recently come across a number of instances where Local Authorities have borrowed money on the mortgage of sewage farm land, as they are enabled to do under Section 235 of the Act of 1875, to defray the cost of road improvements, erecting permanent buildings, improving the water supply, &c. The provision is an eminently useful one, especially to the smaller Local Authorities, and it may be put into operation for raising money for any purpose whereon a Local Authority is enabled to borrow money under the Public Health Act.

There are many of my readers whose duty it is to exercise supervision over Lancashire and other forms of boilers used for steam raising purposes, and it will be of interest for them to be acquainted with the best methods for raising steam with the minimum consumption of coal and the minimum manufacture of smoke. It is for this reason that I refer to an excellent mechanical stoker which I recently inspected. This stoker is Ransome and Rapier's mechanical stoker for boilers. Its advantages are that a regular, even, and complete combustion is secured. The coal is automatically distributed over the fire every few seconds and in such a manner that no two successive charges fall in the same place, which ensures a bright fire of uniform thickness and perfect combustion, and consequently little or no perceptible smoke. The mechanism is excellent, and is not liable to rapid deterioration by contact with the furnace, as is the case with some stokers. The firm assure me that since the introduction of the mechanical stoker in question the steam production has been nearly doubled, whilst some firms allege an increase of 75 per cent. I am unable to describe the principles and mechanism in this column, but would advise those who are interested in the subject of the generation of steam and the reduction of smoke to get the required information from the makers, whose London offices are at 39, Victoria-street, Westminster, S.W.

It is a singular and inexplicable circumstance that no Government department is so indifferently conducted, and the ordinary conditions of business management are so utterly neglected, as the War Department. Why common-sense administration and government should be at such a discount is a problem which is unsolvable. I do not refer to any mal-administration during time of war. This is bad enough to be sure, but take as an example a set of conditions which prevail in time of peace, and which conditions are readily understood by a municipal engineer. Whenever the Department requires a contract for the supply of stoneware pipes, the tenders are to be submitted on a specification which is characteristic of unpractical men, *minutiæ* relating to colour, thickness, length, &c., being elaborated with a puerile precision which, as a consequence, increases the price to an extraordinary degree. The usual stock sizes of 4in., 6in., and 9in. pipes, such as are specified by the ordinary or "garden" engineer are despised, but pipes of 5in., 7in., and 10in. only are those which the Royal Engineer in his wisdom will specify. Of course this means a very considerable increase of price, but this is an unimportant detail. During the process of manufacture the War-office has a representative on the premises of the manufacturer whose expenses have to be included in the price of the pipes, and they have also to find him a number of attendants. Each pipe is tested as to thickness, colour, length of pipe and collar, trueness of section internally and externally, resistance to fracture, &c. &c., and if the variation from the specification, be at all discernible the pipes — which being unusable by others than the War Department — are rejected, and have to be broken up for they cannot be sold. The consequences are that the nation has to pay almost 200 per cent. more for this frivolity than is necessary, for the cost of testing alone as carried out is more than the value of the pipes, and on an average about 200 pipes are tested per day, and then these pipes are sent out to the Gold Coast or Jamaica to be laid by natives. It is devoutly to be wished that the Department would appoint a Lipton or a works manager to cleanse this Augean stable, and run it on business and common sense lines. In referring to Government departments let me say that the opinion of manufacturers and others who have to deal with them is that the Post-office Department is one of the best managed of Government institutions, and I am pleased to give its engineers their meed of praise. Senex.

CAUSES OF THE HIGH INFANTILE DEATH-RATE CONSIDERED.

In an article contributed to the *Englishwoman's Review*, Miss Florence J. Greenwood, Sanitary Inspector, deals with the above question. The title of her article is, "Is the High Infantile Death-rate Due to the Occupation of Married Women?" But in our opinion the real gist of Miss Greenwood's remarks would have been more clearly indicated by the addition of the words, "in factories and workshops," for this, in reality, is what she means. Miss Greenwood says:—

The eradication of erroneous ideas is a process both troublesome and difficult. They are generally so rooted in ignorance and prejudice that they crop up again and again after one might have supposed them to be entirely extirpated.

One such idea, which is firmly fixed in the minds of many people, and I fear will die hard, is that the high infantile mortality which takes place each year in our large towns is entirely due to the occupation of married women in factories and workshops.

Another is that if married women were forbidden by law to work, the death-rate of infants would at once decrease.

It is the object of this paper to show that sweeping statements of this kind are not in accordance with facts, and that such a measure as the one suggested would cause far greater and more widespread suffering than

already exists. It is true that students of vital statistics are concerned with the fact that although the death-rate of the country is being reduced (which is eminently satisfactory), the birth-rate is declining at an even greater rate; and, further, that the death-rate of infants under one year of age is enormously high—25 per cent. of the total number of deaths in England and Wales during the past ten years occurring during that age period.

The question of the high infantile mortality is a difficult and complicated one. It is due to a variety of causes, and a high percentage of occupied mothers may be one among them; but as Dr. Willoughby, in a paper on "Some Prevalent Fallacies in Vital Statistics," says:—"A very prevalent source of error in questions of this kind is the fallacy of ascribing to one particular cause, perhaps a real and powerful factor, but still only one among others not less powerful, the whole effect of a plurality of causes."

But is the occupation of mothers such a powerful factor?

Miss Clara Collet, in her reports on the employment of women and girls, points out (page 7) that the increase in the employment of women during the last decade has been very slight, and that it is due to the entrance of middle-class women into the wages market. Again, on page 27 she says:—"On the whole we seem justified in inferring that in these [factory] towns most affected by married women's labour, the percentage of married women employed is diminishing. Another point is noteworthy. In all these factory districts there is a marked diminution in the proportion of young married women between twenty and twenty-five." On page 27 Miss Collet further says:—"In such towns [Burnley, Preston, Stockport, &c.], where nearly all the girls under twenty, and half the women between twenty and forty-five are engaged away from home, we may naturally look for a high infant mortality, and expectation is justified by the facts."

But Miss Collet has told us that the employment of married women in factory towns is diminishing. We might, therefore, reasonably expect to find that the infantile death-rate, though high, is diminishing; but such is not the case. On the contrary, the Registrar-General's report for 1899 shows that in twenty-seven out of the thirty-three great towns *it has increased* during the past ten years, and in the half-dozen towns where it has decreased, the reduction is anything but a substantial one, while in Burnley it has *increased* enormously. The figures for 1899 in Burnley show 269 deaths under one year of age per 1000 births, being an excess of sixty-one over the average of the preceding ten years.

Are we to infer from this that strangers take better care of the babies than their own mothers? Or is it more in accordance with the experience of those who work amongst these people to say that the ignorant mother knows as little how to rear her child as the ignorant neighbour, and that the higher death-rate is due to other causes?

Miss Collet admits (page 27) that "the high infant mortality rates in Liverpool and Salford, where the percentage of occupied married women is not nearly so high [as in the factory towns], show that a high rate of infant mortality can coincide with a low rate of employment of women away from home."

It would appear, then, that the occupation of married women is not so important a factor as has been supposed, and the evidence of experts bears this out.

Miss Greenwood's contention points to negligence in the care of children as the predisposing facts in infantile mortality. Some opinions of experts in corroboration of this view conclude the first instalment of the article, which is interesting as being a woman's view of what is essentially a woman's question.

THE USES OF COMPOBOARD.

The introduction of a new material as a substitute for natural wood, which, in addition to possessing unique qualities and a wide range of adaptability, is at the same time sanitary, possesses claims upon our notice, which although it appeals mainly to builders and architects, we can hardly afford to ignore. The material in question is known as Compoboard, as it is, as its name implies, of a composite nature. Its basis, which forms its core or inner part, consists of a serried range or course of slats of well-seasoned and carefully-selected wood, each 1in. wide and $\frac{7}{16}$in. thick, cut perfectly plane and true, and cemented together edge to edge with a special fire-proof substance, which forms also the adhesive for the densely-condensed pulp boards by which the range of wood slats are covered at top and bottom—that is, on each side of the board. The materials thus arranged are subjected to immense pressure, and thus compacted into the most perfect union. The resultant Compoboard is a perfectly plane, rigid, solid, and homogeneous material, which can be sawn, nailed, screwed, glued, and, in fact, treated in every respect as if it were simple wood, with the advantage that whereas natural wood will warp, shrink, crack, split, and bulge, Compoboard is tractable, durable, and adaptable, in every respect.

In ceilings, one of the great difficulties confronting the builder is to get a surface that will not crack when there is traffic above or vibration from machinery. Compoboard gets over this difficulty, and ceilings treated with it may be distempered, papered, or finished off with any decoration, however heavy. It can be fitted without any truss or press, and there is no waiting while the stuff dries before it can be painted and papered. Its lasting qualities added to its appearance render it invaluable wherever the ceilings of warehouses, schools, factories, and public institutions are concerned.

In regard to walls, Compoboard is a first-class non-conductor of sound, and thus eminently suitable for partitions. For lining iron and wooden buildings nothing could be more appropriate. Changes of temperature fail to affect it—no small consideration in hospitals abroad, where otherwise openings or cracks would afford a lodgment for vermin. The homelike appearance of a plastered interior is also infinitely preferable to matchboarding, which Compoboard seems destined to supersede. Whenever alteration and repairs are necessary the efficacy of this well-tried material is beyond question, and has already been demonstrated in every direction; in fact, it is questionable whether any recent invention appealing to the building world has met with such instantaneous and unqualified approval.

We understand that the demand for Compoboard, already enormous, is steadily increasing, and it has already commended itself to the War-office and other Government departments. The railway companies are also largely using it for lining the better class of carriages; in fact, its all-round utility is little short of wonderful.

The space at our disposal is too small to do this subject justice, but we feel sure that any inquiries addressed to the British Compoboard Company, 18, Roscoe-street, Golden-lane, London, E.C., will be promptly dealt with.

Jacob Memorial.—It is proposed by many friends of the late Dr. Archibald H. Jacob, Dublin, to raise a memorial in testimony of his life-long work in the interests of the profession. Subscriptions may be forwarded to Sir Charles Cameron, C.B., 51, Pembroke-road, or L. H. Ormsby, Vice-president, R.C.S., 92, Merrion-square West, hon. treas., or to G. F. Blake, Registrar, Royal College of Surgeons, Stephens' Green West.

Public Works.

SEWERAGE.

THE Buckhurst Hill Urban District Council is requiring £2700 for works of sewage disposal.

THE West Bromwich Corporation contemplates a loan of £15,000 for the establishment of sewage works upon the bacterial system.

THE Rural District Council of Doncaster has under discussion schemes of sewerage and sewage disposal for Askern, Bawtry, and Bentley-with-Arksey.

A LOCAL Government Board inquiry was held at Maidenhead recently with reference to the Town Council's application for sanction to borrow £5000 for the extension of the bacteria treatment at the sewage outfall.

A LOCAL Government Board inquiry was held at Leicester last week, with reference to the appointment of the Corporation to acquire land for a sewage pumping station, &c., for the Belgrave District of the Borough. The Town Clerk (Mr. J. Bell) informed the Inspector that it was proposed to abolish the present sewage farm at Belgrave, and to pump the sewage up through a rising main to the Beaumont Leys Farm. There was no opposition.

AT a special meeting of the Armagh Urban Council held last week, a discussion took place regarding the carrying out of the sewerage scheme. The Town Clerk reported that there seemed to be a grave mistake in the levels of the pipes laid at the rear of the houses in Edward-street, and a consequent error in Mill-street. So far as he could see, the plans as contracted for were undergoing a remodelling. He called attention to these as the consequent expense would be serious. After hearing Mr. Peel's report, and considering the whole question, the following resolutions were unanimously passed:—"That this Council being in charge of the funds entrusted to it for sanitary and other purposes, hereby resolves that no extra work or works not directly set out in the specifications, plans, and sections in connection with the new sewerage scheme and disposal works shall be undertaken or begun without first being submitted to this Urban District Council." "That Mr. Parry be brought to Armagh immediately in connection with the Town Clerk's report and that Mr. Peddie is notified to attend, with Mr. Parry."

THE Selby Urban District Council having at a recent meeting resolved to oppose the Leeds Corporation (General Powers) Bill in so far as it proposes to empower the Corporation to purchase the Gateforth Estate for the purpose of establishing thereon a sewage farm, the necessary town's meeting was held last week at Selby to decide whether or not approval should be given to the proposed opposition. Mr. Scott, as chairman of the Waterworks Committee, stated that the cost of the opposition might be large, but it was possible the Leeds Corporation might withdraw the proposal. The Urban Council would not go to law if it could avoid it by some arrangement by which its interests would be safeguarded. It might be that the cost would have to be borne by the Corporation. Were the Selby Authority obliged to construct fresh waterworks, the cost would probably be £15,000 or £20,000. The nearest place from which they could obtain water in that event was, he was advised, Market Weighton. If the Corporation was prepared to suggest any plan by which the risk could be avoided, by which the Selby water would be secure from injury, or by which they would be entitled to compensation in case of injury—these were matters of detail—the Selby Authority would be only too glad to treat with them. It was finally resolved to approve the opposition of the Bill.

THE Newhaven Rural District Council is obtaining a loan of £1800 for Rottingdean drainage.

COL. MARSH held an inquiry on behalf of the Local Government Board recently into the application of the Hornsey, Tottenham, and Wood Green District Councils for permission to borrow £5620 in addition to the £75,000 which the Alexandra Palace Acquisition Act gives them power to provide without the sanction of the Local Government Board.

A FURTHER joint conference of the delegates appointed by the different District Councils in the Western Valleys of Monmouthshire for the purpose of deciding upon a scheme or schemes for draining the locality was held at the Abercarn District Council offices last week, the object being to meet the engineers, Messrs. Beesley, Son, and Nichols, who were appointed at the last meeting to consider and report to the conference on the matter. The County Surveyor explained briefly what it was the engineers were required to report upon. He said there had been one scheme before the county for a considerable time, and that was a trunk sewer right down the Valleys. The conference wished the engineers to go into the whole question and see which scheme was advisable. They wanted them to consider the septic tank or any other system which, as the result of a survey of the whole surroundings, the engineers might consider best. If they recommended one particular scheme the conference desired to have good reasons from the engineers for recommending it. It was finally agreed that the different members of this conference should form sub-committees in each district which they represented to consult with the engineers.

THE latest news received from Sydney, New South Wales, is to the effect that an inquiry was being held by the Public Works Committee into the expediency of constructing a system of sewerage for Newcastle, Hamilton, Wickham, Carrington, and Merewether. Dr. Dick, Medical Officer of Health, was giving evidence as to the character of the City Borough's existing sanitary arrangements. The sewers, he said, had apparently been laid in a haphazard fashion, and many instances of extremely bad construction had been brought to light. The workmanship was certainly not of the best, not even passable. In many instances the joints between the drains and the sewers were grossly bad. Bindings of rags and string to keep the pipes in position had been adopted in some cases, and the bye-laws of the Council even provided that clay might be used in making the joints. There was no plan of the household drains, and great difficulty in locating them was often experienced. Nuisances were created at the places where the sewers emptied into the harbour. It was optional with householders whose premises were not connected with the sewers how often they had sanitary services rendered, and the witness gave shocking examples of neglect or inadequacy in the matter.

WATER.

THE Plympton St. Mary Rural District Council has a large scheme of water supply under its consideration.

A LOCAL Government Board inquiry has just been held at Battle with reference to the application of the Urban Council to borrow £5000 for works of water supply.

THE Corporation of Tamworth, on behalf of the Tamworth District Waterworks Committee, recently presented a petition to the Local Government Board to issue a Provisional Order to empower it to put in force, with reference to certain lands required by them for purposes of water supply, the powers of the Lands' Clauses Acts with respect to the purchase and taking of lands otherwise than by agreement. The inquiry was held on Tuesday last by Colonel C. H. Luard, R.E., at the Town Hall, Tamworth.

The Foleshill Rural District Council has received a communication from the Local Government Board sanctioning the application of a loan for £1000 by the Council for Bedworth boring.

The directors of the Weardale and Shildon District Water Company have decided to recommend a dividend of 6 per cent. for the past half-year, which, with the interim dividend of 5 per cent. last July, will make the dividend for the year 5½ per cent., as compared with 5¼ per cent. last year.

The ultimatum of the West Riding County Council, calling upon the Thorne District Council to provide a new water and sewage scheme, has not been received with good grace by those villages directly affected. The scheme is estimated to cost not less than £7000, a quarter of which has to be raised by landowners.

At a special meeting of the Matlock Urban Council held recently the report of the experimental artesian boring for a new water supply for the town was received. It stated that a depth of 200ft. had been attained. Asked as to the maximum of the experiment, the Clerk said it was to be 300ft., but at 200ft. they had good prospects of getting to water.

The Derwent Valley Water Board Bill has just come before Mr. Campion, one of the Examiners of the House of Commons, for proof of compliance with the Standing Orders relating to the introduction of private Bills. There was no opposition at this stage, and the necessary formal proofs having been given, the Examiner decided that the Orders had been duly complied with. The Bill will accordingly in due course be reported for first reading.

Rugby Water and Improvement Bill came last week before Mr. Campion, one of the Examiners of the House of Commons, for proof of compliance with the Standing Orders relating to the introduction of private Bills. There was no opposition at this stage, and the necessary formal proofs having been given, the Examiner decided that the Orders had been duly complied with. The Bill will accordingly in due course be reported for first reading.

A special meeting of the New Mills Urban Council was held last week in regard to the proposal of the Council to promote a Bill in Parliament for powers to procure a water supply for the district, and construct waterworks near Hayfield. The business was transacted in committee. In compliance with a requisition, signed by twenty ratepayers, the Chairman of the Council has issued notices convening a public meeting for the purpose of receiving the consent of the owners and ratepayers to the Council's opposition to the Bill promoted by the Stockport Corporation to take the waters of and construct waterworks at Kinder; and also to authorise the New Mills Council to pay the cost of opposing the same in Parliament.

The South Essex Waterworks Company has deposited a Bill, under which power is sought to raise £375,000 additional share and loan capital, partly for the purpose of constructing additional waterworks and for the sinking of two further wells in the parish of Ilford. The new capital, of which £300,000 is to be raised by the issue of ordinary or preference shares, is to be offered by auction or tender. A clause in the Bill, of an unusual character, proposes to empower the urban districts of Illford, Barking Town, Grays Thurrock, and Romford, and the rural districts of Orsett and Romford, to borrow money for the purpose of paying the costs incurred by them in opposing this company's Bills of 1899 and 1900, and also for promoting a Bill, which was rejected, to acquire the undertaking of the company. Another clause proposes to authorise the company to pay out of capital its own costs of promoting its Bills of 1899 and 1900, and of opposing the Bill of the District Councils.

At the last monthly meeting of the Heywood and Middleton Water Board the Clerk reported that the Water Bill had been certified as complying with the Standing Orders of the House of Commons, and is included in the first fifty Bills to come before the Committee in the next session of Parliament.

Mr. M. K. North, Local Government Board Inspector, held an inquiry at Danbury last week into the application of the Chelmsford Rural District Council for sanction to borrow £4430 for the purpose of water supply in the parishes of Danbury, East Hanningfield, Little Baddow, Rettendon, Runwell, Sandon, and Woodham Ferris.

Lydford village water supply has not yet reached perfection. Since the water was turned on a few weeks ago two or three of the standpipes have burst, owing to the frost. None of the eight standpipes are protected, although the taps protrude very much, and there are no sinks or gutters to prevent the waste running over the roads.

The Hay (N.S.W.) Municipal Council has decided to improve the water supply by adopting the recommendation of the Government Engineer to erect two new duplex pumps to lift 40,000 gallons per hour, a new boiler, and an additional storage tank of 100,000 gallons capacity. The plant will be placed near the irrigation pumping station, and the water will be pumped direct from the river. The estimated cost is £6800.

At Tuesday's meeting of the London County Council a joint report, presented by the Water and Public Health committees, dealt with the series of new regulations which were adopted by the water companies last November, and with regard to which a Local Government Board inquiry is to be held at the Guildhall, Westminster, on February 11th, at 11 a.m. The Borough Councils were invited to a conference on the subject at Spring-gardens, but on account of the death of her Majesty this has been deferred until next Monday, February 4th, at 2 p.m. In the meantime the two committees reported upon the regulations in detail. They pointed out that expensive alterations would be required in existing fittings, at the expense of the owner of house property, that the companies propose to exercise an arbitrary power as to the pattern and position of fittings, including the course of the supply pipe right up to the cistern; and that the communicating pipe outside the house is required to be laid at a depth considerably greater than that of many of the street mains, defects in which have caused so much distress during frosts. The committees proposed that a series of amendments shall be submitted at the inquiry, by which some of the companies' expensive proposals shall be reduced, or shall not apply to efficient existing fittings, or shall be provided at the expense of the companies. They also proposed that in certain cases the Borough Councils, and not the water companies, should have the power to decide as to pipes and fittings.

LIGHTING.

Colonel Durnford held an inquiry at Harrogate last week with reference to the borrowing of £10,000 for electric lighting purposes.

The Scottish Office has decided that the Gas Order applied for by the Paisley Town Council in October last for powers to borrow a further sum of £25,000 for the electric lighting works will be granted on the terms asked, a local inquiry being dispensed with.

The Hartlepool Gas and Water Bill came last week before Mr. Campion, one of the Examiners of the House of Commons, for proof of compliance with the preliminary Standing Orders relating to the introduction of private Bills. There was no opposition at this stage, and the necessary formal proofs having been given, the Bill was ordered to be reported for first reading.

A Local Government Board inquiry has been held into the application of the Bradford City Council for power to borrow £140,000 for the extension of the City Electricity Works.

The Omagh Gas Bill came before Mr. Campion, one of the Examiners of the House of Commons, recently for proof of compliance with the preliminary Standing Orders relating to the introduction of private Bills. There was no opposition at this stage, and the necessary formal proofs having been given, the Bill was ordered to be reported for first reading.

The Gas Commissioners of the burgh of Falkirk have received a lengthy report from Mr. Gillespie, of Glasgow, who was called in by the Town Council to advise as to the suitability or otherwise of the Thornhill and Parkhouse grounds as a site for the new gasworks. He stated that he had no hesitation in recommending Thornhill site, provided the necessary railway accommodation can be arranged on suitable terms.

The Alfreton Urban Council is alive to its position in regard to the supply of electricity. It is seeking a Provisional Order from the Board of Trade for the purpose of supplying the town with electric light, while at the same time another move is being made in Parliament contemporaneous with the Council's application. A Bill is being promoted entitled the Derbyshire and Nottinghamshire Electric Power Company, and this is giving the Alfreton Council some anxiety. After consideration the Council has decided to oppose the Bill.

The Crawley Gas Company, Limited, has deposited a Bill for incorporation as a statutory company with powers to supply gas within the parishes of Crawley, Ilfield, and Worth, which is an area proposed to be supplied by the Horley District Gas Company under its deposited Bill for next session. The capital of the Crawley Company is proposed to be fixed at £20,000, which comprises £10,000 capital already raised, and £10,000 which is proposed to be raised as additional capital under the powers of this Bill. The dividend of 10 per cent. on the original capital is to be made dependent on a sliding scale based on a standard price of 4s. 9d. per 1000 cubic feet.

Either the Dalkeith Town Council has been living in blissful ignorance, or Messrs. Crompton and Co., who were to have lighted the burgh with electric light, have made a gross mistake, says the Edinburgh *Evening Despatch*. The Dalkeith Councillors in May of last year approved of a scheme by which light would be supplied at 3d. per Board of Trade unit, and by which the company would establish a complete installation at their own cost, even to the extent of erecting the arc and other lamps to be used in the public lighting. Now Messrs. Crompton and Co. intimate that they intended to supply the electric energy only at 3d. per unit. All the calculations of the Councillors have been upset, and a special meeting will be called for an early date, when a protracted discussion is likely to ensue.

A new system of electric lighting has just been perfected by Nikola Tesla in New York. Each lamp consists of 20ft. of glass tubes in rectangular form, wires and carbon filaments being entirely dispensed with. Under a full current of electricity the lamp has the colour of ice in the sun. The light is absolutely steady, closely resembling sunlight. The *New York Herald*, describing Tesla's discovery, says:—"Tesla's oscillator, which is employed in producing the new light, causes electric vibrations of inconceivable speed. These vibrations turn the atoms of the gases in the tubes into so many little comets, which shoot through enclosed space with tremendous rapidity, leaving trains of light behind. This sudden starting and stopping of the current produces continuous light, not of incandescent or arc-light character, but purely solar. In other words, each little lamp is a little sun."

After paying for the past half-year a dividend at the statutory rate of £4 8s. per cent. per annum, the Board of the Gaslight and Coke Company will carry forward a balance of £221,570.

At a special meeting of the Lowestoft Town Council, last Friday, Councillor Fry (chairman of the Electric Lighting Committee) informed the members that they would be ready to switch on the light by February 12th, and proposed to do so on that day.

Owing to the great increase in the number of electric light consumers, the St. Pancras Borough Council has decided to build another light-generating station at Kentish Town. This will make the third station. The Council desires statutory powers to lend fittings to consumers, and a conference of Local Authorities with that end in view is to be arranged by the Council.

The inhabitants of Shotton have taken a very wise step in deciding to light the district, it being intended to carry out a complete scheme of public lighting. At present lamps are lighted along the main road, and shortly additional lamps will be placed in the side streets. The district is rapidly increasing, and an excellent class of house property has been erected, and other houses are in course of construction.

In view of the attempt which is being made at Manchester by the Chairman of the Corporation's Gas Committee to secure for the gas consumers the benefit of a portion of the £50,000 profit which is annually handed over to the City Treasurer in relief of the general rates, special interest attaches to a Government return just published, giving minute financial details of all the municipal gas undertakings in the country.

GENERAL.

The Chiswick Urban District Council is taking steps to obtain a site for public baths.

A public meeting has been held at Ealing for the purpose of urging the municipalisation of hospitals.

The Board of Trade has sanctioned the borrowing of nearly £200,000 for the construction of tramways by the Bournemouth Town Council.

The Medical Officer of Health of Liverpool has been requested by the City Council to report the advisability or otherwise of establishing a voluntary system of notification of phthisis with payment to medical men of a small fee.

The Brighton Town Council has received the sanction of the Local Government Board to the borrowing by the Council of £34,652 for ten years for works for street improvements; £2830 for forty years for the purchase of land as a site for public baths; £560 for forty years for the purchase of land for street improvement; and £1100 for purchasing land as a site for a news-room.

In a short time the Fulham Borough Council will have in full operation one of the most important combined schemes of refuse destruction, electric lighting, and disinfection undertaken by a local body in London. Under the existing system the cost of refuse removal by barges is 1s. 11d. per load, which, on an average yearly collection of 40,000 loads, amounts to £3833. By means of the new destructor the cost, it is believed, will amount to only £2358, showing a net profit on the destructor of £1775. By using the destructor in connection with the new electric lighting works the burning of the refuse will be equal to the consumption of 2000 tons of coal, which, taken at 16s. a ton, shows a still further profit to this municipal undertaking of £1600 a year, and a still further saving of 500 a year is estimated to be made by combining the disinfector with the destructor and electric lighting schemes. Allowing 5¼ per cent. as interest on the sinking fund, the estimated net profit on the combined scheme is put down at £2728 per annum.

The Rochford Rural District Council has accepted a tender of £3810 for the erection of the hospital for infectious diseases, which it has decided to provide jointly with the Shoebury Urban District Council.

The Chailey Rural District Council has joined the East Grinstead Urban Council in a resolution calling upon the County Council to provide accommodation for the reception of small-pox cases occurring in East Sussex. The Newhaven Rural District Council, however, will take no action in the matter on the score of expense.

A Local Government Board inquiry was held in Liverpool last week relative to the application of the City Council to borrow £53,500 for the erection of labourers' dwellings wherein to re-house the tenants of insanitary property. The scheme was opposed on behalf of the Liverpool Property Owners' and Ratepayers' Association.

The Examiners of Private Bills of the House of Commons resumed the investigation of Standing Order proofs last Friday. Among the measures considered were the Notting-hill Electric Lighting, Bridewell Hospital, City and Brixton Railway (Extension of Time), Metropolitan District Railway, King's-road Railway, and the District Messenger and Theatre Ticket Company Bills. The total number of Bills to be examined prior to introduction and first reading is this year 235, and of these 209 have now been dealt with, the remainder being down for consideration last Monday, together with a few which had been postponed.

A meeting of the Huddersfield Chamber of Commerce was held last week. A deputation from the Yorkshire Electric Power Syndicate, including Mr. A. G. Lupton (chairman, Leeds), to solicit the assistance of the Chamber towards securing a parliamentary Bill, waited upon the Council. The Leeds Chamber of Commerce had promised to support the Bill by evidence if necessary. It was not a directors' or promoters' company, and its sixty shareholders were distributed all over the county. The capital at present was only £10,000 for the purpose of the promotion of the Bill. It was decided that before the Council passed any resolution on the subject, a deputation should wait upon the Huddersfield Town Council to ascertain how far the scheme would affect the Corporation.

Dr. E. H. Young, Medical Officer of Health for Okehampton, in his annual report to the District Council, says:—"For some little time past the United Devon Association has been taking steps in various directions to make the county more known to holiday makers and those looking out for a fixed place of residence. This desirable endeavour could and should be materially assisted by the Sanitary Authorities throughout the county, improving the health conditions of the people under their care. One of the most important ways of doing this is by systematic inspection of a district. As I have before pointed out, the visit of the Sanitary Inspector not only leads to improvement of the house and its surroundings, but is at the same time an object lesson in the cause of sanitation. For the first five years that I was your Medical Officer of Health you had had one Inspector (Mr. Hooper) who did nothing else but sanitary work. The taking over of the roads led to a change. Two Surveyors were appointed who were also Sanitary Inspectors. After five years' experience of each of these arrangements I feel sure that more sanitary work was done in the former period than in the latter. Both Mr. Hooper and Mr. Smale were hard-working, able and conscientious men, but with the amount of road work under their control, work which must be attended to, as it was constantly under survey, the time available for sanitary work was reduced to small proportions. It would be advisable to go back to the old plan of leaving one man for sanitary work only, even if it was necessary to keep two for roadwork."

The Ilford Urban Council desires to enlarge the Isolation Hospital, at an estimated cost of £9445, by providing accommodation for twenty-six beds. The number of beds in the hospital at present is twenty.

The Sanitary Authorities in Leeds are taking the utmost precautions as to the detection of, and dealing with, cases of bubonic plague. The lodging-houses and canal boats are very closely watched, and their owners and occupiers have been circularised on the subject.

On Tuesday the Secretary for Foreign Affairs notified to the Hull Sanitary Committee the receipt of a notice from the Netherlands Government to the effect that Hull had been officially declared infected with plague, and that the provisions of the Venice Convention would be applied to any vessel which left Hull ten days or less before January 21st last.

Dr. Cameron, the Medical Officer of Health for Leeds, has issued a notice to keepers of lodging-houses, masters of canal boats, and others, asking them to notify any case of plague which may occur on their premises. He reminds them that while plague in some of its forms is very easily recognised by the glandular swellings (wax kernels) it is by no means easy to detect it in all cases. It is therefore desirable that parties receiving into their houses any person suffering from a severe attack of what might be considered influenza, from any illness of the nature of inflammation of the lungs, blood poisoning, or any obscure symptoms of a feverish description, should immediately obtain medical assistance, and if there should be any suspicion on the part of the medical man called in that the disease might be some obscure form of plague to at once report the matter to Dr. Cameron.

Dr. W. K. Bullmore, Medical Officer to the Falmouth Urban Sanitary Authority, has just issued his annual report, in which he states that the improvement of the sanitary condition of the district had been the very earnest desire and the successful aim of the Authority. All the suggestions that had been made from time to time had been carefully considered, and, as far as practicable, carried out. He attributed the remarkably low death-rate to the improved dietary of infants, which had been largely brought about through suggestions thrown out from time to time by the Authority. Referring to the water supply, the Medical Officer states that it is a very fair sample of surface water, and has been certified as quite wholesome by some of the best-known analysts. It occasionally contained at certain periods of the year a peaty deposit, which went to show that a better system of filtration was necessary. During the year 350 children had been vaccinated, but no prosecutions had been taken under the Act.

The report presented by the Highways Committee at the meeting of the London County Council on Tuesday was principally concerned with tramways. The Committee proposed to transfer in relief of rates from the profits on tramways a sum of £40,000 on account of the £80,500 for which allowance was made in the estimates. The receipts of the South London tramways for the past three years were given. In 1898 (the last year under the company) they were £431,352; in 1899, £439,310; and in 1900, £441,408. Of last year's receipts, £8443 were from the all-night services. The Committee propose to invite representatives of the Borough Councils to a preliminary inspection of the specimen electrical car and plant at the Council's Camberwell depôt on February 14th. It is proposed also to construct immediately two short lengths of tramway in North London, already authorised—one along Crowndale-road, connecting the King's-cross and Euston routes to the north, and the other in Agincourt-road and Constantine-road, Hampstead, relieving the traffic along Fleet-road to Hampstead Heath.

PERSONAL.

Mr. H. Allen has been appointed Medical Officer of he Crediton union.

Mr. A. J. Troughton has been appointed Medical Officer for Bentham.

Dr. Dwight Morris has been reappointed Medical Officer of Health for Sunbury.

Mr. H. J. Marten has been appointed Surveyor for the eastern district of Wandsworth.

Mr. S. Davies has been appointed Medical Officer of Health for the borough of Woolwich.

Mr. Sumner has been appointed Sanitary Inspector for Driffield, at a salary of £100 per annum.

Mr. P. Dodd has been appointed Surveyor for the western district of the Wandsworth borough.

Mr. L. J. Veit, of Barrow, has been appointed Engineer and Surveyor for the urban district of Goole.

Mr. R. J. Angel has been appointed Borough Surveyor for Bermondsey, at a salary of £500 per annum.

Dr. Peter Thompson, of Owens College, Manchester, has been appointed Lecturer on Anatomy to the Middlesex Hospital Medical School.

Mr. William H. Roberts, fitter in the Broughty Ferry Gasworks, has been appointed Manager of the gasworks at Newtownards, Ireland.

Dr. Young has been unanimously reappointed Medical Officer for Rochford, and Mr. C. E. Judd has been reappointed Inspector of Nuisances.

Mr. Charles Brown, Burgh Surveyor, Airdrie, has been appointed Borough Surveyor and Sanitary Inspector for the burgh of Hawick, at a salary of £210 per annum.

The Local Government Board has sanctioned the reappointment of Mr. O. Osborne as Medical Officer of Health for the urban district of Bexhill, at a salary of £50 per annum.

The Local Government Board has sanctioned the reappointment of Messrs. Taylor and Dale as Medical Officer of Health and Inspector of Nuisances for Smallburgh, respectively.

Dr. Dudfield, of Paddington, has been temporarily appointed to carry on the duties of the Medical Officer of Health for the City until the late Dr. Sedgwick Saunders' successor is appointed.

Dr. William Collingridge, Medical Officer of Health of the Port of London, has come forward as a candidate for the office of Medical Officer of Health for the City, rendered vacant by the death of Dr. Sedgwick Saunders.

Mr. J. Harper, assistant valuer to the London County Council, was on Tuesday appointed chief of the Statistical Department, in succession to Mr. Gomme, promoted to the Clerkship of the Council. The commencing salary is £900 per annum.

A brass tablet has been erected in St. John's Church, Woking, to the memory of the late Sir Richard Thorn-Thorne, K.C.B., F.R.S., F.R.C.P., Medical Officer of Health to the Local Government Board, by the members of the Medical Department of the Board "as a mark of the esteem and regard in which they held their chief, and in appreciation of his services to the nation."

Dr. Dudfield, Medical Officer for the Borough Council of Kensington, has had his salary raised from £900 to £1000 per annum, the rise being sanctioned by the Local Government Board, on condition that he gave up all other income, or rather, agrees to confine his services to the Council. He has, in pursuance of this agreement, given up his position as Poor Law Medical Officer to the Board of Guardians.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2076.—Women Sanitary Inspectors: Salaries Paid.—"W." writes:—"Some time last year a return appeared in your columns of the women appointed, and the salaries paid as Sanitary Inspectors, Health Visitors, and Workshop Inspectors. Would you kindly give me the reference to this return, as I have not been able to trace it through the index?"

Answer.—The return referred to appeared in our issue of June 23rd, 1899, Query 1512, and gave a list of towns where Women Sanitary Inspectors are appointed, and the salaries paid to such Inspectors.

2077.—Examination for Inspectors of Weights and Measures.—"J. J. G." writes:—"I should be much obliged if you would inform me if there is any institution where I might take a preparatory course, which will cover the subjects required for the Board of Trade examination for Inspectors of Weights and Measures."

Answer.—There is no institution to our knowledge which provides a special course of instruction for persons studying for the examination referred to. A course of tuition by correspondence through the post is obtainable, and to be recommended, and an advertisement by a professional coach has from time to time appeared in our columns.

2078.—New Sewerage System: Connecting Old Drains to Sewer.—"H. D." writes:—"I enclose sketch showing a number of houses, the drainage of which was to cesspools. The distance of the houses is more than 100ft. to the new sewer. Is it the duty of the Local Authority to lay the sewer or otherwise?"

Answer.—We assume that the Local Authority are constructing a new sewerage system, and the question is directed to ascertain whether the owners of the houses now drained into the cesspools can be required to connect their drains into the new sewers. If we interpret the query correctly, which is very indefinitely put, we have to state that if the existing drains to the houses are sufficient for their effectual drainage, although drained into a cesspool, it will be the duty of the Local Authority to connect the drains to the sewer under Sec. 24 of the Act of 1875, and for that purpose to construct such a sewer as may be necessary.

2079.—Sanitary Association of Scotland: Certificate.—"J. W." writes:—"Will you please advise whether the Certificate of the Sanitary Association of Scotland would be recognised by Local Authorities in England, when applying for a post as Sanitary Inspector?"

Answer.—The certificate of the Sanitary Association of Scotland is, so far as a test of a candidate's sanitary knowledge is concerned, of equal value with that of a certificate by a similar English body. But such certificate does not testify to the candidate's knowledge of the Public Health Acts (England), and in this respect a candidate for an English position is somewhat at a disadvantage. It is impossible, of course, for us to determine whether a Local Authority would look upon the Scotch certificate as equal to that of an English one. It is generally prescribed that candidates for vacancies for Sanitary Inspectors under the Public Health Act, 1875, should possess the certificate of the Sanitary Institute, but this is not always insisted upon, and the querist may apply for such vacancies.

2080.—Knackers' Yards: Licensing of, Vested in District Councils.—"Leo" writes:—"(1) By Sec. 27 (2) of the Local Government Act, 1894, the powers, duties, and liabilities of Quarter Sessions in relation to the licensing of knackers' yards are transferred to District Councils, and I believe these powers are contained in the Knackers Acts, 1786 and 1844. (2) Would you kindly say whether any parts of these Acts have been repealed, or whether the whole of them are now in force in rural districts? I refer more especially to Sec. 14. Will you also please state whether Sec. 14 could be held to exempt horse slaughterers who buy dead or live horses, cut them up, and sell hides, bones, flesh, &c., for profit?"

Answer.—(1) The licensing of knackers' yards is transferred to Urban and Rural District Councils by Sec. 27 (2) of the Local Government Act, 1894, and, as the querist rightly assumes, the Knackers Acts, 1786 and 1844, apply. Secs. 1, 2, 7, 13, and 14 of the Act of 1786 only are in force, and Secs. 1, 2, and 10 of the Act of 1844. (2) By Sec. 14 of the Act of 1786, the Act does not apply to any currier, fellmonger, tanner, or dealer in hides. It does not appear that a horse slaughterer who amongst other

DRINK PURE WATER

Physicians say 95 % of our countrymen and women fill their system with poison, lime, acid, minerals, old age matter, contained in raw water. Debility, nervous afflictions, skin and blood diseases, malaria, typhoid fever, are often the direct result of drinking impure water.

THE '**GEM**' PURE-WATER STILL is a perfect, hygienic, automatic apparatus, which will make the foulest water clear and sparkling, and remove all mud, lime, sewerage, microbes, and poisons. It is better than the most expensive filter, and should be used by all who value health. Send for pamphlet containing valuable information, or order a Still at once. AGENTS WANTED.

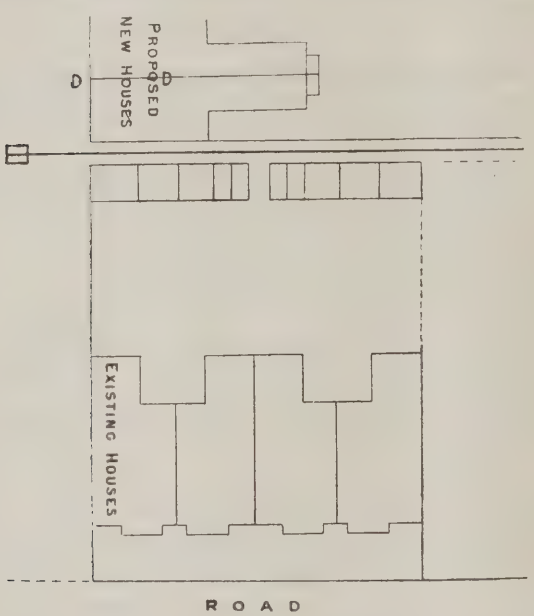
things buys dead and live horses, cuts them up, and sells hides, bones, flesh, &c., for profit, is exempt from the operation of the Acts.

2081.—Old Highway becoming New Street.—"Clerk" writes:—"I submit plan showing an old highway alongside which four cottages were erected in 1898. At the same time the foundations of a new road were laid along the flank of the end cottage. While these were being erected, the land on the opposite side of the new road was sold, and the road was left 30ft. wide. Did the erection of the four houses constitute C a new street? My Council have before them a plan for two new houses at D on the same side of the street as the end of the four cottages



abuts on. These two houses have a frontage to the road. Can the Authority refuse to pass the plans on the ground that their erection would constitute the road a new street of less width than that required by the bye-laws? The estate is altogether a new one, and there is no other erection of any kind thereon. I may add that at the time the erection of the four houses was commenced, the bye-laws relative to the construction of new streets and buildings had not been confirmed by the Local Government Board. The bye-laws now in force require streets to be 36ft. in width. The street previously referred to has not been made beyond the foundations being put in for a width of 30ft."

Answer.—It is a question of fact for the determination of the magistrates as to when a person is laying out a new street. Decided cases are very conflicting. In the case before us houses are being built on one side of a street, the width of which—if the evidence of a paved foundation may be accepted as determining such—is only 30ft., while the width of a new street as required by the bye-laws should be 36ft. No houses are being or have been built on the opposite side of the street. The proposed new houses are in line with the flank wall of the existing house. In our opinion, the Authority would not be well advised in refusing approval of the present plan on the ground that the owner is laying out a new street of less width than that required by the bye-laws. The proper course for the Authority to adopt is to ensure that, when the owner of the land on the opposite side of the street proposes to build, and submits his plans, the proper width of 36ft. be provided.

2082.—Power to Restrain Keeping of Fowls: to be Restrained by Private Act: Information Required.—"K. W. J." writes:—"The Corporation of this town are preparing a Bill to be submitted to Parliament with the object of obtaining additional powers for various improvement schemes. The sanitary department would like a clause inserted in the Bill giving them power to prohibit (under any conditions) the keeping of fowls in yards of dwelling-houses, the keeping of such not being conducive to health and cleanliness. Are you of opinion that the Sanitary Authority would be successful in their application for such powers, or do you know of any Corporation where such powers are in operation? I should be glad of any information."

Answer.—Whilst we are of opinion that the keeping of fowls in populous urban districts should be regulated by bye-law, we are of opinion that the Legislature would hesitate before giving a Local Authority power under a private Act to entirely prohibit the keeping of fowls in the yards of all dwelling-houses. The Local authority's law officers might, however, in the case named by the querist, draft a clause in the Bill enabling the Authority to regulate the keeping of fowls at a certain distance from dwelling-houses, and as to the prohibition of their being kept in yards of a restricted area. We do not know of any case where the powers named have been obtained by private Act. We shall, however, be greatly obliged if any of our correspondents can supply the information.

CHAPTER XVI.—TRANSFORMERS.

We have already mentioned that the electric unit of power, the volt-ampère or watt, equal to about $\frac{1}{746}$ of a horse-power, is the product of one volt and one ampère. Thus the power of a current of 100 ampères at 10 volts pressure is one kilowatt equal to about $1\frac{1}{3}$ horse-power, and the power of a current of 10 ampères at 100 volts pressure is also one kilowatt.

The sectional area of the wire along which a current is conducted is dependent on the ampères of current; thus to conduct a current of 100 ampères a copper wire having an area of about 50 square millimetres is required; whereas to conduct a current of 10 ampères an area of about $2\frac{1}{2}$ square millimetres is sufficient, quite independently of the voltage of the current.

The power which can be transmitted electrically by means of a wire having a given area varies, therefore, with the pressure or voltage of the current; thus, along a copper wire having an area of 50 square millimetres, equivalent to about a quarter of an inch diameter, one kilowatt, equal to $1\frac{1}{3}$ horse-power, can be transmitted with a current at 10 volts pressure; or 10 kilowatts, equal to $13\frac{1}{3}$ horse-power, with a current at 100 volts pressure; and 100 kilowatts, equal to $133\frac{1}{3}$ horse-power, with a current at 1000 volts pressure.

These figures are only approximate, and meant to show the relation that exists between the powers that can be transmitted at different voltages, as no general rule can be laid down for determining the size of a wire to conduct a given current; since, owing to internal resistance, the wire becomes more or less heated, with a consequent loss of current.

By increasing the sectional area of a wire its conductivity is increased, and there will be less current absorbed in the shape of heat.

It is obvious that there will be a greater loss in conducting a current along a very long wire than along a very short one, and the loss is proportional to the length of the wire; so that if the conduction of a current along a very short wire results in a certain percentage of loss, whereby the wire becomes appreciably warm, by increasing the length without increasing the sectional area of the wire a point will eventually be reached where the whole of the current is absorbed in the shape of heat, and none is available for other purposes.

The main point to be considered in determining the size of the wire, where a current has to be conducted a very long distance, is the capital which must be spent on the conducting wire, and to what extent this may be increased to minimise the loss of current in the wire by increasing its area, so that the money representing the extra current obtained thereby covers the interest on the extra outlay. This is, of course, a very complicated matter, and requires very deep and careful calculation.

From the foregoing it will be clearly understood that to conduct a current of electricity to any considerable distance economically a high voltage must be employed, so as to reduce the quantity of copper in the wires as much as possible.

On the Continent and in the United States of America currents of as high a voltage as 10,000 or 12,000 are by no means infrequently used for transmitting power electrically to very great distances, and there are instances where even 30,000 volts are attained. There are isolated instances of continuous currents being employed for transmitting power to very great distances at very high voltages reaching up to 15,000, but it is impossible with one machine to generate a continuous current of such a high voltage as this. In such cases several generators must be used connected in series, so that the current generated by the first passes on to the second, and from this to the third, and so on, the voltage being increased as the current passes through each successive machine, but the difference of potential between the positive and negative terminals of any one machine may not exceed about 2000. And in the same way at the receiving station, where the current is conducted, it drives a number of motors connected in series.

In Switzerland, where a continuous current of 14,400 volts is generated at Combe-Garrot and conducted a distance of twenty kilometres to Chaux de Fonds, nine generators are used, connected in series, so that the difference of potential between the positive and negative terminals of any one generator does not exceed 1800 volts, and at the receiving station the motors work with a maximum difference of potential of 600 volts between each of their positive and negative terminals.

It is possible, although difficult, to construct good dynamos to generate a continuous current of 2000 to 3000 volts, or even more, but the difficulty of effectively insulating these machines and constructing them so that no sparks are formed at the commutator is so great, and involves a so much greater cost, that such high voltages cannot be generated economically, nor is this of very great importance in these days, when alternating currents can be generated so easily to serve the same purpose, namely, to transmit power from one place to another at a very great distance away, and when alternating machines have reached such a high state of perfection.

The employment of such high voltages is, of course, not without some considerable danger connected with it which must be carefully guarded against, as a shock might result in instant loss of life or permanent disablement of a person, and the insulating material surrounding wires in contact with metals or other conducting substances must be very perfect, as it is otherwise very liable to be punctured by the current in its endeavours to force itself a way through and escape.

For general motive purposes or for driving motors which require to be frequently reversed a continuous current of from 100 to 500 volts is most frequently and satisfactorily employed.

Incandescent lamps are now made giving satisfactory results when used with a current at 220 or even 250 volts, but the life of the lamps is shortened to a prohibitive extent by raising the voltage beyond this. The most common voltage for lighting with incandescent lamps is 100, and it is only within the last few years that manufacturers have been able to put on the market a durable and efficient lamp for use on 220-volt circuits. Alternating currents can be generated at a much higher voltage and with greater ease than continuous currents, for the sensitive part of the continuous-current generator, namely the commutator, does not exist in the alternating machines, as these have only simple slip rings and brushes for collecting the current.

There is also another reason why alternating currents can be generated advantageously at a very high voltage, whereas continuous currents cannot. A high-voltage current is only advantageous in transmitting power between two distant places, on account of the saving that can be effected in the conducting wires, but for use in the ordinary way for motive purposes it is extremely inconvenient, as well as dangerous, and for lighting purposes altogether impracticable. With alternating currents the voltage can be raised or lowered with the greatest ease by means of transformers which have no rotating parts, consequently require no attention and have also a very high efficiency; that is to say, there is only a very slight loss of power in transforming an alternating current from a high to a low voltage, or *vice versâ*.

A current is generated at, say, 2000 volts, and by

means of transformers this voltage is raised to, say, 30,000, so as to economise in the wires necessary to conduct the current to a receiving station at a far-distant town where it is to be utilised for lighting purposes. At the receiving station the current of 30,000 volts is transformed into one of 2000 volts, and in that state conducted to the different houses, at each of which it is again transformed to 100 volts, so as to be suitable for lighting with incandescent lamps. In this way a great saving is effected in the conducting wires, and inside the town the voltage is kept down to within reasonable and convenient limits.

Transformers for continuous currents are combinations of a dynamo and a motor, and have consequently the disadvantages of both, besides being comparatively expensive machines. The motor receives the current at a high or low voltage and drives the dynamo, which is wound to generate a current of the required voltage.

For example, a 100-kilowatt machine generates a continuous current of, say, 100 ampères at 1000 volts pressure, which must be utilised for lighting purposes a considerable distance away.

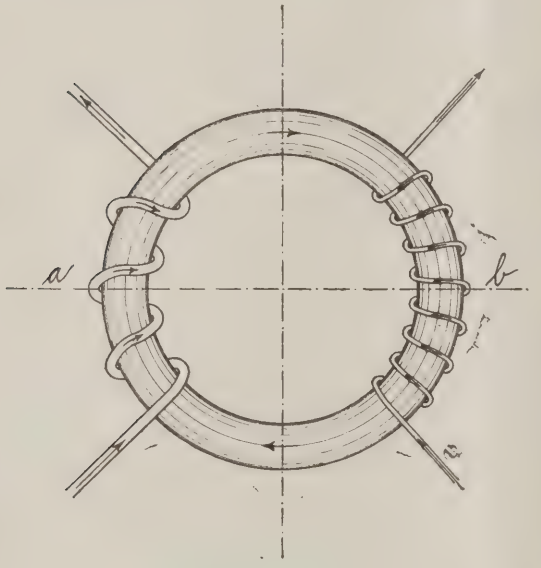

Fig. 27.

This current drives the motor-dynamo, which transforms it into one of nearly 1000 ampères at 100 volts pressure, there being some loss of power due to the internal resistance of the machine itself. Rotary transformers consist sometimes of two separate machines, a dynamo and a motor, mounted on one base-plate and firmly coupled together; but usually a special machine is used furnished with a double armature having two separate sets of coils with two commutators mounted on one spindle, one half working as a motor and causing the spindle to rotate while the other half works as a dynamo and generates a current. These machines can also be made for driving with an alternating current and generating continuous, or for driving with a continuous current and generating alternating.

For altering the voltage of alternating currents stationary transformers are used, which are altogether unlike the rotary transformer for continuous currents, having no working parts whatever, consequently they have a very high efficiencey and require no more attention than the conducting wires.

In its simplest form this class of transformer consists of an iron ring having a primary and a secondary coil of insulated copper wire wound round it in the manner shown in Fig. 27. The two ends of the primary coil *a* are connected with the positive and negative terminals of a generator so that a current passes through the wire forming the coil, causing lines of force to circle round it, which travel through the iron ring and magnetise it.

As the magnetic lines of force traverse the portion of the iron ring where the secondary coil *b* is wound they are intercepted and cut through by the wires, thus causing opposing lines of force to circle round them, and a current of electricity to flow through the secondary coil *b*.

Coil *a* receives its current direct from the generator, and is therefore primary, whereas the secondary coil *b* receives its current by induction.

If both coils consist of an equal number of turns round the iron ring, the same number of lines of force which circle round the wire forming the primary coil and which magnetise the iron are cut through in the same time by the wire forming the secondary coil, and the induced or secondary current will be theoretically exactly the same as the primary.

If the secondary coil has more turns than the primary the voltage of the secondary current will be higher than the primary; for a greater number of lines of force will be cut through in a given time by the secondary coil than are emitted from the primary coil, but the ampères of the secondary current will be less than the ampères of the primary, the product of the volts and the ampères or the watts being theoretically the same in both the primary and secondary currents. If, on the other hand, the primary coil has a greater number of turns than the secondary, the voltage of the secondary current will be lower than the voltage of the primary, but the ampères will be increased.

In the figure the coil *a* consists of four turns and *b* consists of eight. Assuming that *a* is the primary coil having a current of 20 ampères at 100 volts pressure flowing through it, the current induced in coil *b* will be nearly 10 ampères at 200 volts pressure. There will be some loss of power due to the resistance to the electric current in the coils and to the magnetic lines of force in the iron core, and some also due to the fact that not all the lines of force are utilised for inducing a current in the secondary coil, as some manage to escape through the air instead of through the iron core and past the secondary coil.

Transformers of this class are merely practical applications in their simplest possible form of the principles enumerated in Lenz's law. That is to say, an alternating current flowing through a coil of insulated copper wire, surrounding a piece of iron, constantly magnetises it alternately in opposite directions, and causes a constant change to take place in a magnetic field in relation to an electrical conductor placed within its influence, namely, the secondary coil, and thereby produces by induction an alternating electric current in the secondary coil.

It is clear that if a continuous current were to flow through the primary coil an alteration in the magnetic field in relation to the electrical conductor forming the secondary coil would only take place at the instant when the current is turned on or off, thereby momentarily inducing a feeble current in the secondary coil. These transformers, therefore, can only be used with alternating currrents.

Properly constructed transformers for alternating currents of from 5 to 200 kilowatts have an efficiency of about 93 to 98 per cent., the larger ones having a higher efficiency than the smaller. That is, about 2 to 7 per cent. of the current is lost in the process of transformation through the internal resistance of the machine when used with the full current for which it is constructed, but when used with a weaker current the percentage of loss is considerably greater.

(*To be continued.*)

TUBERCULOSIS—INFECTION, HEREDITY, PREVENTION, HYGIENIC TREATMENT.

By A. G. Young, M.D., Secretary State Board of Health, Maine, U.S.A.[1]

INTRODUCTORY.

The purpose of the following paper is to teach that tuberculosis is a preventable disease, and that, in the early stage particularly, it is curable. The mortuary statistics which have been compiled in various places since the significance of the discovery of Koch's bacillus has received general recognition by medical men, show very clearly the preventability of tuberculosis. At the last congress for the study of tuberculosis held in Paris, Professor Grancher[2] declared that pulmonary tuberculosis is the most curable of chronic maladies; and M. Jaccoud,[3] the eminent professor of the Ecole de Médécine, Paris, long recognised as one of the best authorities on pulmonary diseases, taught that "curable as tuberculosis is by the fibroplastic process while in the crude state, and during the whole period of softening, it is so also when ulceration occurs and caverns form. The knowledge that recovery is possible under these circumstances dates from ancient times; the facts which established both the truth of this statement and the anatomical mechanism by which it occurs are classical, and there is no need to insist now upon these points."

But before the full significance of the truth of the preventability and the curability of this disease can permeate the mind of the lay or professional thinker, and can move communities to more than half-hearted and half-successful efforts to stamp out the pestilence, correct ideas must prevail in relation to the questions of infection and of heredity. The full truth about the infectivity of tuberculosis and the limitations of the influence of infection can have no other than an assuring and helpful influence. The continuation of the erroneous dogma of heredity as a predominant factor in the causation of the disease is an incubus which paralyses the patient's hope of cure, and stays the hand of private and public benefaction.

The mortality from tuberculosis.—Among all the infectious, epidemic, or pestilential diseases, tuberculosis is the most terrible destroyer of human lives; in most civilised countries it is, indeed, the cause of a larger number of deaths than are caused by all the other infectious or so-called zymotic diseases combined. In the State of Maine, while the mortality from the whole list of the other infectious diseases[4] was 6266 deaths during the seven years 1892-98; the disease tuberculosis alone, in its various forms, destroyed 9735 lives in the same period.

The social and economic aspect.—Of the 9735 deaths from tuberculosis, 8429 of them fell victims to pulmonary tuberculosis, popularly called consumption. Of these 8429 persons who died of consumption, there were about 6480 between the ages of 15 and 60.[5] These persons may therefore be said to have died during their industrial or productive age, when death entails the greatest loss upon the family and the State. How serious the financial and social burden of tuberculosis is but few persons stop to think. Assuming that the average value of each of these 6480 persons would have been only 500 dols. each if they had not been cut down, we find that over 3,000,000 dols. of the State's productive capital has been swept away—more than enough to cancel the whole indebtedness of the State. Add to this the loss of labour due to partial or total disability for a prolonged period before death, the loss of labour by relatives and friends, the cost of medical attendance and nurses and medicines during illness; the value of the other 3255 lives lost by tuberculosis and not included in the foregoing conservative estimate, and the incidental expenses of their illness, and the cost runs so high into the millions that it should serve to "stagger humanity," as a present much-quoted prediction puts it. And even this is not the whole tax levied and collected by this one disease, tuberculosis. It has been estimated that for every person who dies of tuberculosis five recover.

INFECTIVITY.

The question of infectivity.—As to the fact that tuberculosis is an infectious, or communicable disease, there should no longer be a question even among the non-professional classes. Most intelligent persons know something of the infectiousness of tuberculosis, although few understand the full significance of the fact—that practically the whole terrible prevalence of the disease in the human race is due to infection. On the other hand, much which is now known of the infective agent and of the ways in which infection occurs, is assuring. Of the extent of the danger of infection and of the limitations of the danger, it will be the object of the remainder of this paper to explain.

The infective agent.—The essential cause of this disease is the bacillus of tuberculosis. It is a micro-organism of slow growth, whether inoculated into artificial culture media by the bacteriologist, or implanted in the human body through inhalation or otherwise. This characteristic favours the infected body in affording time for the rallying of the defensive forces of the organism. On the other hand, the germ of tuberculosis has, in quite a marked degree, the power of resisting or surviving the action of many natural and artificial agencies which have a tendency to destroy most disease germs. This increases the sphere of mischief of the bacillus by prolonging the period during which rooms or clothing, for instance, may remain infectious and dangerous, after they have once become infected. How long the bacillus will retain its virulence in dried sputum is a question of much practical importance. In the experiments of Schill and Fischer[6] its infectiousness was retained 95 days; in other experiments its virulence was partly lost in 186 days, and wholly gone in 226 days, or seven months and a-half. Dr. Pietro De Toma[7] found that dried sputum preserved its virulence nine or ten months under favouring conditions, but that under less favourable conditions the life of the tubercle bacillus was destroyed in a much shorter time. The conclusions of Sormani[8] are that the bacillus, whether dry or moist, retains its virulence for at least two months. Cornet[9] believes that we may assume that the bacillus of tuberculosis in dried sputum loses its virulence within three months on the average, but may retain its infectious attributes six or eight months under some circumstances. An observation of Dr. H. C. Ernst[10] indicates the possibility that the virulence of this germ may sometimes be preserved much longer than is suggested by the work of the preceding investigators.

Tuberculous sputum stood in jars in his laboratory nearly four years. The dried-up sputum, nevertheless, still contained living virulent bacilli.

Other questions.—The answers to some other questions also serve as a guide in choosing unobjectionable methods of disposing of tuberculous matter. As a general rule the infectivity of the tubercle bacillus is lost more quickly in moist than in dried sputum. The bacillus is overrun and destroyed by the ordinary bacteria of putrefaction. Falk, Baumgarten, Fischer, and Toma found that its vitality was lost in water in a few days at ordinary temperatures. Galtier,[11] however, learned that the virulence of the bacillus in small fragments of putrefying tubercular tissue in water was maintained from 8 to 17 days. Low temperatures merely inhibit the development of the tubercle bacillus, but its vitality remains unimpaired after exposure to intense cold, or prolonged freezing and thawing. The most potent of natural agencies in the destruction of tubercular infection is light. Exposed to direct sunlight the bacillus in sputum is, according to Koch, destroyed in from a few minutes to a few hours, depending upon the thickness of the layer of material to be acted upon. Dr. Migneco, of Italy, and Ransome and Delépine fully confirm the statement that light, particularly direct sunshine, is a rapid disinfectant of tubercular matter. Diffused light has an influence in the same direction, but acts much more slowly.

Infection as a cause of tuberculosis.—Infection is not only the predominant cause of tuberculosis, but, so far as concerns the prevention of the disease or the prognosis of recovery from it, infection may be considered as the exclusive cause. In the past, heredity was assigned a prominent position among the causes of tuberculosis, but now a large majority of the most eminent medical practitioners and teachers are convinced that direct heredity is but a small etiologic factor, while most of the cases of tuberculosis are referable to infection.

Of the ways in which the tubercular parasite finds an entrance into its host, and starts a new infection, only the most important—the most frequent—will be mentioned in this paper. By far the greatest number of infections are the result of inhaling the bacillus in dried tuberculous sputum.

The danger of infection by inhallation and its limitations.—The prodigality of Nature in her provisions for the perpetuation of the lower species of organisms is nowhere more apparent than among the bacteria. "Dr. George A. Evans, in a paper read before the King's County Medical Society in 1894, gives the result of some experiments made by Dr. George F. Nuttall, of Johns Hopkins University, that in the sputum of three cases undergoing the Koch treatment the number of bacilli expectorated in the first case in twenty-four hours was 2,000,000,000, in the second case the number varied between 20,000,000 and 165,000,000 on the days preceding the Koch inoculations. In another case not undergoing the Koch treatment the number of bacilli varied between 300,000,000 and 4,000,000,000. According to Bollinger, one cubic centimetre of phthisical sputum contains from 810,000 to 960,000 bacilli; the average consumptive, therefore, expectorates between thirty and forty millions of these parasites a day."[12] According to a statement of Dr. Netter,[13] some phthisical patients expel from their lungs in the course of a day as many as 720,000,000 bacilli.

It is fortunate for the human race that limitations are imposed upon the infectivity of the bacillus of tuberculosis and upon the chances of infection. Many tuberculous persons are not dangerous to their associates, for the reason that the bacilli remain within enclosed cavities, or are so discharged that there is no liability of entering other bodies through the usual portals. But among patients expectorating infection in plentiful quantities, the character of the patient increases or lessens the danger of infection. While the careless and dirty patient who spits upon the floor or into his handkerchief endangers all persons who are much with him, the presence of the cleanly person who is scrupulously careful in the disposal of his sputum may endanger not even his most intimate associates. And even with careless persons the intensity of infectiousness, or the concentration of infection, diminishes very rapidly with the increasing distance from the patient, even within the same house or room.

In the process of tubercular infection there are two contending factors which must be taken into account. One is the morbific capabilities of the slowly-developing tubercle bacillus. The opposing force in the struggle is the resisting power of the organism which is invaded—the power of the system to destroy the invading parasites and cast them forth. The infection of the living organism and the extension of the infection is not the mere implantation of germs in an indifferent culture medium; it is a struggle for supremacy between the invading parasites and their host. In the majority of cases, as pathological studies indicate, the infected human organism is victorious and rids itself of an incipient tuberculosis which is often never suspected.

The outcome of the struggle depends not alone upon the resisting powers of the person who has received the infection, but it is largely influenced by the quantity of infection received and by the virulence of the bacilli. Thus it is that the occasional visitor to an infectious patient is but little endangered, while there is much danger of the development of tuberculosis among his more constant associates. As to the virulence of the bacilli, investigation has shown that it is modified in various ways. It is intensified or lessened according to the media or host in which it had previously developed. It had diminished and finally destroyed with age and especially by the action of light, as has already been said.

CORRESPONDENCE.

THE INSTITUTION OF CIVIL ENGINEERS.

(*To the Editor of* The Sanitary Record.)

Sir,—To prevent your general readers from assuming from the remarks of "Senex" that every candidate who passes the examination for election to associate membership into this Institution is eligible for election at once, I quote the following from the "Minutes of Proceedings of the Institution of Civil Engineers," viz., vol. cxxxi., page 10:—"It is to be borne in mind that the Institution examination for the class of associate member may be passed by a man before he is in a position by age or otherwise, to be actually a candidate for election."

I may say that there are many who have passed the examination and are qualified by age, but not otherwise, waiting for election.

With respect to restriction of membership, I beg to say that the total number of every class on the roll of the Institution on the 2nd of January, 1896 (the year previous to the examination referred to), was 6794. The total number on October 1st, 1900, was 7272.

I merely write this because I have a liking for your paper, and you always rectify any wrong impression you have given, consequently I thought that either "Senex" or yourself would do so in this case. I am caring for your readers; the Institution of Civil Engineers can care for itself.—Yours faithfully, O. J. K.

Batley, February 2nd.

Coming Municipal Men.

XIX.—MR. FRANK FOWLER,

Assistant Surveyor, Staines Rural District Council.

Mr. Frank Fowler, the subject of our present sketch, was born in Bedford, and educated in the Bedford Modern School. He served his articles under Mr. William H. Leete, A.M.I.C.E., M.S.I., M.I.C.E., &c., County Surveyor of Bedfordshire. At the expiration of his articles, Mr. Leete's two senior assistants having obtained appointments, he was selected to fill the office of chief assistant, which position he held for 2¼ years. The County of Bedford contains 138 parishes, comprised of three Municipal Boroughs, four urban districts, and seven rural districts. It is 31 miles long, 25 miles broad, has an area of 303,500 acres, and, according to the last census, a population of about 170,000. In the year 1894, there were about 400 miles of main roads under direct control, supervision, and maintenance, but at the present time that mileage reaches the considerable extent of 730 miles. The rateable value is £925,043, while the expenditure for the last few years has been between £40,000 and £50,000 per annum for improvements, maintenance, and repair. It will thus be seen that Mr. Fowler has had wide scope for practical works of many and varied types. During the 6¼ years he was at Bedford, he gained considerable experience with sewerage, drainage, building, road making, and other works. He assisted in preparing schemes for sewage works for the Dunstable Town Council, and the Trustees of the Three Counties Asylum, Arlesey; bridge works at Oakley, Potton, Flitwick, Leighton Buzzard, Barton, Radwell, Cardington, Harlington, Harrold, &c., and designing plans for Public Pleasure Ground at Bedford. In the extension of the Shire Hall, consisting of the enlargement of the Council Chamber, offices, and accommodation for the Inspector of Weights and Measures, and Secretary of the Technical Instruction Committee, he was also actively engaged, together with a new police-station and cookery school at Luton, a farm school at Ridgmont, and a store depôt building at Kempston, with accommodation for smithy, carpenters' shop, stables, and stores for four rollers, vans, carts, tools, &c.; this, in addition to drainage, fencing, paths, and other works in all parts of the county. He prepared three 2in. scale maps of the county, showing the different class of roads, railways, river, towns, villages, &c., also alterations of county boundary to date.

MR. FRANK FOWLER.

In July last year Mr. Fowler was appointed temporarily to the office of Assistant Surveyor to the Urban District Council of Sutton, Surrey, under Mr. C. Chambers Smith, C.E., M.S.I., where his knowledge of building superintendence was still further extended, as may be gathered from the fact that he was entrusted with the supervision of new buildings under the byelaws relating to new streets and buildings. He also had very useful experience under the Private Street Works Act as regards plans, estimates, provisional apportionments, &c. He moreover had the advantage of acquiring an insight into the working of the bacterial system of sewage treatment, and superintendence of extension work to fitters, &c., for which Sutton has by its successful treatment become world renowned. He has had, in addition to a practical experience, a thorough training in county and municipal office routine both at Bedford and Sutton. On the termination of his appointment at Sutton, he was selected and appointed Assistant Surveyor to the Staines Rural District Council, under Mr. Geo. W. Manning, C.E., Engineer and Surveyor, the position he now holds.

Health Matters in the City.—At a meeting of the Court of Common Council held last week, at the Guildhall, the Lord Mayor presiding, the Sanitary Committee reported that they had appointed Mr. Reginald Dudfield to act in the place of the late Medical Officer of Health, Dr. Sedgwick Saunders, for two months, pending the appointment of a successor, and recommended that it be referred back to them and to the Officers and Clerks Committee to consider the duties and emoluments of the positions which, in their opinion, should be held in future by different persons. This was agreed to. The Court discussed a report of the Streets Committee, recommending in regard to the street refuse of the City that the principle of barging dust and refuse into the country be adopted, and that they should be authorised to obtain a suitable site for the purpose. It was stated that the Corporation had to deal annually with 75,000 loads of refuse, of which 45,000 were already barged down the river. A letter was read from the Lambeth Borough Council, strongly objecting to the City's bringing into and shooting within another district their refuse matters. To this the committee had replied that they had instructed their Inspectors to see that such work was carried on with great care, and the offensive matters removed with due despatch. Mr. W. H. Williamson said that at Upchurch and other places on the Medway, to which dust and refuse was barged, diphtheria was very prevalent. There was the greatest difficulty in getting rid of the refuse and dust, and the only remedy was to burn it.

HOUSING OF THE POOR IN RURAL DISTRICTS.

A REPORT ADOPTED IN JULY LAST STILL INOPERATIVE, NO LAND BEING AVAILABLE.

The Annual Report of Dr. John C. Thresh, Medical Officer of Health for the Maldon Rural Sanitary District, &c., contains a report of two members of a Parliamentary Committee, appointed to hold a public inquiry at Bradwell-on-Sea into an application of the Maldon Rural District Council for permission to adopt Part III. of the "Housing of the Working Classes Act, 1890." The signatories to the Report remark that as the application is the first of its kind in the County of Essex, and any decision which the County Council might adopt would be likely to influence the conduct of other Rural District Councils within the county, they considered it right to make a full report, as there was little doubt that the conditions existing at Bradwell-on-Sea existed in many other places also.

The Report states:—

The inquiry was held in the elementary schools on Saturday, March 10th, and there was a good attendance of the larger ratepayers, including the rector, the County Councillor for the district, some of the Rural District Councillors, and some of the Parish Councillors, but the labouring class was almost unrepresented.

Prior to the opening of the inquiry we inspected a number of cottages under the guidance of Dr. Thresh, who is Medical Officer of Health for the district, as well as for the county. The first dwelling visited was a vile place—a wooden building, in wretched repair, having only two rooms (one upstairs and one down), no scullery of any sort, and no sink; with an open grate, without an oven, as the only cooking place; a small patch of garden and a privy completed the accommodation, for which 1s. 6d. weekly rent was being paid. The next cottage of similar construction, though scrupulously clean, was in even worse repair, the upper room being uninhabited; the widow occupying it had only made the lower room habitable by papering the walls to keep the wind and rain out. We visited other cottages, not so bad as these, but, nevertheless, much out of repair, which would have been condemned by Dr. Thresh, if there were any other place for the occupants to go to. We saw several others unoccupied, and more or less in ruins—their construction having been of the flimsiest character and repair out of the question.

A detailed description of every cottage in the parish, showing the accommodation, number of occupants, and its condition, was handed in at the inquiry by Dr. Thresh, and some further particulars concerning the unoccupied cottages have been furnished since at our request.

Plans for twelve cottages were submitted by the Surveyor, on behalf of the Maldon Rural District Council, and the approximate cost estimated at £2500, including the land, but no site has been determined upon. No exact estimate of the annual expenditure likely to be entailed by this scheme was submitted to us, but it was proposed to let the cottages at 3s. per week, and it was thought this would involve an annual loss of about £50. From calculations made by ourselves, however, we arrive at the conclusion that, with a rent as low as 3s. per week, the annual loss is likely to be even greater, and probably at least £80.

It was explained, on behalf of the Rural District Council, that it was doubtful if any higher rent than 3s. could be paid by any of the labouring class, and certain persons present urged that even this figure was too high, and that only 1s. 6d. per week could be paid.

This brings us to the crux of the whole difficulty. Nobody can build a decent cottage to let at 1s. 6d. per week. Many of the cottages attached to the farms, and let to the labourers employed thereon, are undoubtedly let at a rent much below their real value. One case of this sort came to our knowledge in detail during the course of the inquiry. Two cottages had been built by the landowners, for a farmer, at a cost of £400, the farmer paying them rent at 4 per cent. on the outlay, as well as paying rates and taxes, and keeping them in repair. We calculate that this involved him in an annual expenditure of about £22, equal to about 4s. 6d. per week for each cottage, but he only charged his men 1s. per week for each of them. In other words, the men's real wages were 3s. 6d. per week higher than their nominal figure, and he succeeded in retaining his men without appearing to break the local wages rate.

If the farmers would charge a rent representing the real value, and pay a proportionately higher wage, there might be some chance of private enterprise stepping in to provide the necessary cottages, but the present system destroys private enterprise, and if it be persisted in, the housing conditions in places like Bradwell must continue to grow worse, and the tendency towards the depopulation of the rural districts be increased.

On the other hand, if the Local Authority provide Housing accommodation for the agricultural labourers at rents suitable to their present wage, it must involve a heavy loss to the rates, the burden of which will fall, not merely on the owners and occupiers of the farms where the labourers work, but also on the professional man, the small shopkeeper, and others forming the general body of ratepayers in the district. In other words, farm labour will be subsidised at the public expense. But though this may form an argument for altering the incidence of the burden, its consideration does not help to meet the present difficulties, and the mere fact that the loss will fall on the general body will tend rather to retard necessary action by Public Authorities than to encourage rash speculation by them, and there appears, therefore, to be little reason to exercise a restraining influence, when such a case comes before us well supported by local opinion.

There can be no doubt that such exists in this district. The Parish Council of Bradwell are anxious for the adoption of the Act, and they are strongly supported by the rector, who is himself the owner of the living and a considerable ratepayer. The Rural District Council of Maldon have adopted the proposal, and are the applicants for the County Council's permission to move in it.

On the other hand, the farmers, with one exception, who spoke at the inquiry, were opposed to the scheme, apparently on two grounds, (*a*) that their men could not pay a rent of 3s. weekly, and (*b*) that any probable site was likely to be too distant from their own farms to be of use to their own men. One ratepayer objected *in toto*, declaring boldly that no more cottages were required, and that two of his own were empty. With regard to the assertion that more cottages are not required, we can hardly think that, if such were the case, the farmer already mentioned would have gone to so much expense to induce his landlords to erect two new cottages.

Some evidence was adduced to show that certain bargemen, earning better wages than the agricultural labourers, might probably be glad to take the proposed new cottages at rents involving the parish in a smaller loss than shown by the Surveyor's estimate, and that, in such case, the cottages now occupied by them would become available for other families earning less.

After carefully considering the whole of the facts, we are satisfied that the cottage accommodation in

Bradwell-on-Sea is inadequate, and that the conditions under which many of the labouring class are compelled to live are conducive neither to morality nor to good health.

In our opinion accommodation is necessary in Bradwell-on-Sea for the housing of the working classes, and there is no probability that such accommodation will be provided without the execution of Part III. of the Act; and having regard to the liability which will be incurred by the rates, it is, in our opinion, under all the circumstances, prudent for the said Maldon Rural District Council to undertake the provision of the said accommodation, and we recommend that the certificate asked for be granted accordingly.

We think the burden of the expenses should be borne by the contributory place of Bradwell-on-Sea as general expenses under the Public Health Acts, being satisfied that the circumstances of the contributory place and of the rest of the district render such limitation just.

We are of opinion, by reason of the date of the next ordinary election of members of the Maldon Rural District Council and otherwise, that Section 55 (1) (*a*) of the Act should not apply, and that the Rural District Council should be authorised to adopt Part III. of the Act forthwith as a case of emergency.

Dr. Thresh remarks:—"The report was adopted by the County Council on July 3rd. Upon receipt of this report the Bradwell Parish Council undertook to find a suitable plot of land for the erection of the cottages, but as yet they have been unsuccessful."

IS THE POPULATION OVER-ESTIMATED?

When Dr. Paine was Medical Officer of Cardiff, says a writer in the *Western Mail*, he expressed an opinion that if he lived long enough he would see the death-rate as low as 16 per 1000. That was a figure which he thought could not be reduced in any large town. Last year, however, the Cardiff death-rate, calculated upon the Registrar-General's return of population, was only 13·7 per 1000, the lowest, probably, in the whole of the United Kingdom for towns with over 150,000 inhabitants. It is no reflection upon Dr. Paine that he was unable to produce such results as his successor. In his days, sanitation had not reached the high standard which is now expected from corporate bodies. There were fewer Inspectors, there was no sanatorium, there was not the same control over the floating population, and the means adopted for isolating infectious diseases were of the crudest description.

In order to show the progress in the health of the town since the first returns of deaths were made, in 1845, the means of ten years will be the most representative. They average as follows:—

1845-54	...	annual death-rate per 1000	...	...	33·1
1855-64	...	,,	,,	...	26·5
1865-74	...	,,	,,	...	23·5
1875-84	...	,,	,,	...	20·0
1885-94	...	,,	,,	...	20·4

It will be seen that the last decade gives a slightly-increased rate over the preceding one, but since 1890 the figures have been exceptionally low, the returns reading as under:—

	Population.	Death-rate.
1890	117,012	21·1
1891	130,283	22·0
1892	136,181	18·7
1893	142,435	19·6
1894	148,890	16·2
1895	155,637	18·2
1896	162,690	16·8
1897	170,063	14·9
1898	177,770	14·8
1899	185,826	15·3
*1900	194,247	13·7

Nothing could be more satisfactory to the Cardiff Corporation Health Committee and the Medical Officer than the steady decrease in the death-rate, but what one naturally puts to himself is the question whether, in the first place, the estimated population is correct; and, secondly, whether there are not circumstances connected with a growing town like Cardiff which tend to reduce the death-rate. Taking the population first, the Registrar-General works out his increase on a system of logarithms based upon the previous ten years. He does not add a tenth for every twelve months succeeding the year in which the census is taken. That would certainly not prove correct, for the simple reason that there is an increase upon an increase, on precisely the same lines as compound interest must be worked out. The system, however, is like the laws of the Medes and Persians — unalterable — although the Local Authorities for at least three years have seen that the figures have been going awry. The Medical Officer (Dr. Walford) has excellent means of approximating the population by the number of inhabited houses. He must, however, be guided by the population per house as recorded in 1891, which worked out at 6·29. This is a rather high average, but, under the circumstances, it may be too low a figure. In 1898, when the colliers were on strike, the working men of Cardiff were placed in a dilemma from which it was difficult to escape. Many householders, after selling their furniture and other marketable articles, found it necessary to take apartments. Some have not been able yet to re-stock their houses, and for this reason the population per house may be greater than it was in the years 1881-91. Taking that as a basis, the Medical Officer (Dr. Walford) found that the Registrar-General began to go wrong in 1897, when he under-estimated the figures by 2050. Since that year the logarithm estimate has far exceeded that worked out from the number of inhabited houses, but even then the death-rate is not materially affected. The figures are:—

	Reg.-Gen.'s return.	Dr. Walford's estimate.
1897	170,063	... 172,113
1898	177,770	... 176,380
1899	185,826	 182,212
1900	194,247	... 185,037

The effect which the Medical Officer's estimate will have upon the death-rate during the last three years will be noticed from the following calculations:—

	Registrar-General. Per 1000.	Dr. Walford. Per 1000.
1898	14·7	... 14·8
1899	15·3	... 15·8
1900	13·7	... 14·4

The sum and substance of these calculations is that the death-rate of Cardiff for the past year should have been, if Dr. Walford's estimate of population is correct, 14·4 per 1000 instead of 13·7. In any case, the rate is as low as could be reasonably expected, and a great improvement upon Dr. Paine's cherished idea of 16 per 1000 inhabitants.

There are several reasons why the Cardiff death-rate should be low, independent of an over-estimated population. The progressive character of the town attracts a number of healthy young men and women who have passed the dangerous stages of infant life. What this means will be appreciated when we point out that in 1900 there were in the town 1314 deaths of persons under 5 years of age (52·78 per 1000 deaths), only 3·11 per 1000 between 5 and 15, and 3·97 per 1000 between 15 and 25. No large town which gains its natural growth of population as between births and deaths could expect such a low death-rate as one to which young people who have passed the dangerous infantile age swarm in order to obtain a living.

INSPECTION OF FOOD IN THE COUNTY OF LONDON.*

The food, other than uncooked butchers' meat, which was seized by the officers of the London Sanitary Authorities, consisted chiefly of fish, fruit, vegetables, eggs, poultry, condensed milk, and tinned foods. The reports show that such food was seized in Paddington, Fulham, Chelsea, Westminster, St. James, Westminster, Marylebone, St. Pancras, Hackney, St. Giles, Strand, Holborn, City, Shoreditch, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, St. Saviour, Southwark, St. George-the-Martyr, Newington, St. Olave, Bermondsey, Rotherhithe, Battersea, Clapham, Wandsworth, Greenwich, and Deptford. In the City 750 tons of fish were condemned at or near Billingsgate. In the Strand district, in which Covent Garden market is situated, considerable quantities of fruit and vegetables were condemned, especially in the hot month of July.

Much attention has been recently directed to the sale of tinned food, and the fact was established during the year that a trade is carried on in which blown tins are punctured and afterwards sealed and labelled so as to make them resemble tins, the contents of which have not by change in condition brought about the blowing or bulging of the tins. The following extract from the annual report of the Medical Officer of Health of Limehouse is of interest in this connection:—

"On February 2nd, accompanied by the Inspector for the No. 3 district, I siezed a large number of tinned goods, lying at No. 3, Sage-street, Shadwell. Knowing that the owner, who was a wholesale merchant, had been previously prosecuted by a neighbouring Vestry, but had unfortunately been discharged, I decided that I should carefully sort each individual tin before proceeding before the magistrate to have them condemned. My plan was this, to divide a parcel of foods into four, allot one parcel to each of the three Sanitary Inspectors, and to sort the fourth myself. Then I carefully examined each tin that had been rejected by the Inspectors so that I could inform the magistrate that each tin which I had seized had been examined by me personally. They included 3971 tins of milk, salmon, sardines, soups, rabbits, compressed beef, vegetables, &c. It was proved conclusively at the Police-court that he was in the habit of buying rejected canned goods from importers for the purpose of feeding pigs. In fact, the invoices that were produced were marked 'pigs' food,' but he failed to show that he had ever sold a tin in his life for pigs' food. The tins, when the contents are bad, become bulged or blown from the formation of the gas produced during putrefaction. These tins were pricked to let out the gas, re-soldered, and fresh labels pasted over. The result was that the tins would appear good and would remain apparently good for two or three weeks. When I made the seizure, several men were employed putting on these labels. The case lasted five days, and Mr. Dickinson having found him guilty, sentenced him to five months' hard labour. It was a very severe sentence, but not too severe, considering the amount of injury the man could do and has undoubtedly done."

The Medical Officer of Health of Bethnal Green also reports that the Chief Inspector has found that an extensive trade is being carried on in unsound tinned provisions. He writes: "These usually are condemned stores disposed of by the owners, ostensibly for conversion into pig and poultry food. We have ascertained that articles of this nature are purchased by dealers who proceed to prick the bulged tins and re-solder them. The old label is then washed off and a new one pasted on. In this state they are disposed of to the keepers of small general shops, and to the manufacturers of cheap confectionery." The Chief Inspector states that unsound condensed milk is used for making caramels and caramel toffee. In connection with a seizure of unsound condensed milk to be used for such manufacture the owner was fined £25. The Inspector, referring to this case, writes: "Since then Inspectors Bridal and Mills, acting under my instructions, seized 125 tins of bad condensed milk at 58, Collingwood-street, and 83 tins of sardines at 71, Cambridge-road. At the time of writing two summonses in respect of these seizures are pending, and I will therefore only add that arising out of them Inspector Bridal proceeded to Islington, and gave such information to the officers of that Authority as resulted in their making a seizure of upwards of 2000 tins of blown sardines, salmon, condensed milk, &c., on the premises of a man who I have reason to believe has been largely engaged in trafficking in unsound foodstuffs of this description."

Inquiries were made by the Medical Officer of Health of Mile-end Old town at a large number of small general shops concerning the condition of tins of condensed milk. At the rear of one shop a quantity of such tins were found which were unfit for food. This milk was condensed, and it was then ascertained that the vendor of the milk lived in Poplar, and was carrying on a similar trade in that district, where he was prosecuted by and fined at the instance of the Local Authority.

In Poplar the Inspector seized seventy-one blown tins of condensed milk. The defendant's assistants admitted that the tins were deposited for the contents being used for the making of caramel toffee, and he was fined £20 with £10 10s. costs. The Medical Officer of Health, writing on this subject, says:—

"I suggested to the Sanitary Committee that it would be advisable to point out to the importers and the wholesale houses the desirability of having tins containing bad condensed milk destroyed altogether, or removed by the Local Authority as trade refuse (more especially as the importers and wholesale houses now pay to have it taken away) and then there would be no possibility of it being used as human food. I stated that it was manifestly wrong that the contents of tins which have practically been given away for pig-feeding or manure should again find their way into the market. It is not only detrimental to the public health, but it is bad from a monetary point of view as it must interfere with the trade of the shopkeepers, and it must also lessen the business of the wholesale houses and importers of condensed milk. The question was asked, Is such milk fit for pig-feeding? But the Public Health (London) Act, 1881, only relates to articles intended for the food of man. The Committee recommended that the various Sanitary Authorities in London be asked to communicate the suggestion to wholesale dealers in condensed milk in their districts.

"On another occasion I reported for the information of the Committee and general public, that it was rumoured that the contents of blown tins containing unwholesome condensed milk, since the recent prosecutions, are emptied into gallon jars, and thus supplied to dishonest pastry cooks, &c., the opening of such tins and the pouring into the jars took place near a pig-stye, as if for pig's food, in order to throw the officers of the Local Authorities off their guard."

Large seizures of tinned foods were made in some other districts. In Bermondsey, 181 cases of condensed milk, containing about 7000 tins, were condemned, the owner being fined £78. In Newington, 5664 tins of condensed milk were condemned; in St. George-in-the-East, three cases of condensed milk were condemned; in Wandsworth, 346 tins of condensed milk, 39 tins of lobster, and 25 tins of boiled rabbit were surrendered; in St. Saviour, Southwark, 400 tins of condensed milk were condemned; in St. Olave,

*From the last annual report of Dr. Shirley Murphy, Medical Officer of Health, London.

7 cwt. of tinned meat and 1 cwt. of condensed milk were surrendered; in Whitechapel, 94 tins of salmon and 28 tins of lobster were destroyed; in St. Pancras, 2112 tins of salmon and 36 tins of sardines were condemned; in Lambeth, 23 tins of lobster were seized, and the vendor fined £10.

From what has been said above it will be seen that there is a distinct trade in which unsound tinned food is prepared for human consumption, but the trade in food of this quality extends to other articles also. Inspections in Mile-end Old-town led to the discovery that a very similar course was adopted in dealing in eggs. The Medical Officer of Health states, that in the course of inspection of houses a large store was found and within an hour after the inspection application was made by the occupier for the removal and destruction as trade refuse of numerous eggs. The premises were then watched and in November were visited by the officers of the Sanitary Authority, who seized cases containing 3400 eggs which were subsequently condemned by the magistrate and the defendant fined £15, with £5 5s. costs. Dr. Taylor writes :—

"Inquiries were then instituted by your Inspector and myself in various parts of London with the result that we found that a very large trade was being carried on with this class of goods, particularly in the East-end amongst the lowest foreign shopkeepers. We also ascertained that the son of the defendant was employed by wholesale provision merchants to "candle" eggs (*i.e.*, to separate the good from the bad), and that he had been allowed to take the bad ones away. In other cases he had purchased eggs as waste at prices varying from 1s. to 1s. 6d. per 100, the price of good eggs at that time being from 7s. 6d. to 8s. per 100. Inquiries were made amongst the small provision merchants in St. George's and Whitechapel, and we discovered a number of them had purchased eggs from the defendant, and a large proportion of these eggs had been purchased by customers as good."

In July the Medical Officer of Health of Limehouse seized 117 tubs of unsound strawberries in two vans in Devonport-street, and took them before the magistrate at the Thames Police-court for condemnation. The magistrate refused to make an order, as no evidence was produced that they were exposed for sale at the time of the seizure, though they had been offered for sale and refused by a jam manufacturer in Ratcliffe half an hour previously. The owner admitted they were unsound, and afterwards made application for them to be destroyed as trade refuse. The Limehouse District Board applied for a mandamus to compel the magistrate to state a case on the ground that a condemnation order was a condition precedent to taking out a summons against the owner of the article, and that all the magistrate had to do upon the application for a condemnation order was to satisfy himself that the article in question was unfit for food of men, that it was not until a summons had been issued that he had jurisdiction to inquire whether the article was intended for the food of man or not; that this was a point of law, and the magistrate was bound to state a case for the opinion of the High Court upon it. The Divisional Court took this view.

The absence of any systematic inspection of meat in London gives abundant opportunity for unsound meat to be sold for human food. London receives from other parts of the country meat which cannot be sold locally on account of its condition, and there is, no doubt, a definite trade carried on in meat of a quality which would never knowingly be allowed to be used in any civilised community. Some time ago I had inquiry made concerning the business of a knacker in one of the provincial towns, with the result that it was found that the flesh of animals which had been sent there was removed to premises in a district in the east of London. The occupier of these premises dealt in cat's meat, but the fact that the flesh he received from the provincial town was dressed in the manner in which flesh is dressed for human consumption, strongly suggested the view that it was intended for this purpose. In 1899 the chief Sanitary Inspector of Bethnal-green kept watch over the London premises where this flesh was received, and ascertained that among the customers of the occupier of these premises was a "manufacturer of high-class meat pies." Having put himself in communication with the officers of other districts, to which this flesh was taken from these premises, a seizure of a portion was made in Hackney, where it was being removed to the premises of a sausage-maker. The flesh was unfit for food, and as the result of proceedings in the police-court the sausage-maker and the cat's-meat dealer were each fined £50. I have reported at length on the need for adoption in London of a system of meat inspection similar to that of many large foreign towns, and the subject still awaits the decision of the Council. Until such system is adopted there is not the least doubt that unsound meat will be freely introduced into London to the prejudice of the poor, who, more than any other class, must suffer from the present want of control over the meat supply.

Foreign meat entering London through the public slaughterhouses of Birkenhead and Deptford is subject to inspection at the time of slaughter, and that which is received into the Smithfield market of the Corporation is also subject to inspection. In 1899 the Medical Officer of Health of the City reports 405,406 tons of meat entered these markets, and 1172 tons were destroyed, of which 1034½ tons were putrid, 95 tons were diseased, and 42½ tons unsound from accident or other causes. Dr. Saunders says of "wasted" Australian sheep many were condemned, and that some of them, though not absolutely injurious as food, were almost destitute of nutritive property. In St. Saviour, Southwark, as many as 1520 carcases of frozen sheep were destroyed, but in the reports relating to the other districts no reference is made to seizure of foreign meat arriving dead in England.

The only other districts in which any considerable seizures were made were Holborn and Islington. In Holborn, where a large meat trade is carried on in shops situated in streets bordering on the City markets, and where a special Meat Inspector is employed, 3390 stone of meat were seized, 888 stone of which were diseased and 3101 decomposed. In Islington, where also a special Meat Inspector is employed, 8014 lb. of meat in slaughter-houses and 1439 lb. of meat in shops were destroyed. The appointment of special Meat Inspectors throughout London is much needed, and especially in districts where the population is poor and low-priced meat is sold.

The Edinburgh and District Water Trust has, on the recommendation of its Works Committee, resolved to make application for an extension of time in which to complete the Yalla Waterworks. Under the Act sanctioning the Yalla scheme ten years were given in which to complete the works. So anxious had the Trustees been that this great work should be proceeded with with vigour, that they gave a bonus of £15,000 to one set of contractors. The work went on pretty well for two years, but afterwards, owing to various circumstances, the contractors were unable to proceed further. Six years will have elapsed by May 30th next, and the Works Committee are informed that scarely one-fourth of the work has been completed. Under these circumstances the Trustees are obliged to apply for an extension of time, and in the Provisional Order to be presented under the Private Legislations Procedure (Scotland) Act, they ask for five years in which to complete the works.

EXAMINATION RESULTS.

THE SANITARY INSTITUTE.

At an examination in Practical Sanitary Science, held at Bristol on January 25th and 26th, 1901, three candidates presented themselves. The following two candidates were awarded certificates:—Walter Stanley Bracher and William Osborn Thorp.

For Inspectors of Nuisances eighteen candidates presented themselves. The following twelve candidates were certified as regards their sanitary knowledge, competent to discharge the duties of Inspectors of Nuisances under the Public Health Act, 1875:—Herbert Arnold, George Bidwell, Frederick James Brown, Edward Carter, William Derham Carter, Alfred Chant, William Henry Greenep, Edward John Ley, Albert Ernest Parker, Robert John Alexander Stuart, David Thomas, Joseph William Tibbitts.

SANITARY INSPECTORS' EXAMINATION BOARD.

At an examination for Sanitary Inspectors under the Public Health (London) Act, 1891, held last month in connection with the above, the following candidates were successful. The names of the Institutions at which the candidates received instruction are appended.

Miss G. D. Bevan (National Health Society), Miss I. W. Cox (National Health Society), Mr. V. E. F. Donnewald (Sanitary Institute), Mr. A. Griffiths (Sanitary Institute), Mr. R. E. James (King's College), Miss G. A. Looker (National Health Society), Mr. C. W. Rudd (King's College), Miss L. L. Spiller (National Health Society), Mr. A. H. Walker (King's College), Mr. A. Wheaton (King's College).

ROYAL INSTITUTE OF PUBLIC HEALTH.

THE COMING CONGRESS AT EASTBOURNE.

Convened and presided over by the Mayor (Alderman H. W. Keay, J.P.), a meeting was recently held at the Town Hall to elect committees to arrange for the meeting of the Congress of the Royal Institute of Public Health at Eastbourne next July.

The Duke of Devonshire will act as president of the Congress, and his Grace and the Duchess will dispense their hospitality on a princely scale. Through the kind offices of the Hon. Mrs. Freeman-Thomas, Lord Brassey has promised to entertain the members of the Congress at Normanhurst.

The Mayor opened the proceedings, pointing out the advantages to the town of such a Congress, with a special allusion to the kindness of the Duke of Devonshire, who had promised to do all he could to render the visit a success.

Alderman Strange also referred to the immense benefit the Congress would be to the town, and moved the following resolution:—"That the Mayor (Mr. Alderman Keay, J.P.) be appointed honorary president of the Congress of the Royal Institute of Public Health, to be held at Eastbourne this year; that the Town Clerk (Mr. H. W. Fovargue) and Medical Officer of Health (Dr. W. G. Willoughby) be appointed joint honorary secretaries; that the Borough Accountant (Mr. John Allcock) be appointed treasurer; and that the foregoing be *ex officio* members of each of the committees appointed."

Colonel Shaw seconded, and the motion was carried.

Dr. James Adams moved:—That the following be appointed the Executive Committee (with power to add to their number) to arrange the places and times of meetings, and to carry out such other duties connected with the Congress as do not appertain to any other committee appointed, viz.: Mr. E. L. Beckwith, Rev. E. L. Browne, Mr. J. P. Cockerell, Rev. Dr. Crowden, Mr. Alderman Duke, Mr. R. M. Gloyne, Dr. Habgood, Mr. Councillor Harding, Mr. F. Hollins, Mr. Councillor Martin, Mr. Councillor Maude, Mr. A. Mayhewe, Major Molineux, Mr. Councillor Rowe, Mr. Councillor Sharpe, Mr. Councillor Sherwood, Mr. Alderman Strange, and Mr. Councillor Wright.

The Rev. Canon Goodwyn seconded, and the motion was carried.

Mr. Arthur Dilks moved that the following be appointed the Reception and Hospitalities Committee, viz.:—Mr. Councillor Breach, Mr. W. Bruford, Mr. Alderman Burt, Colonel Cardwell, Mr. J. P. Cockerell, Mr. Councillor Eden, Mr. Alderman Farncombe, Colonel FitzGerald, Mr. Freeman-Thomas, M.P.; Dr. H. S. Gabbett, Rev. R. C. Gillie, Rev. Canon Goodwyn, Mr. Lindsay Hogg, M.P.; Mr. Councillor Simmons, Mr. Councillor Steward, Mr. Alderman Sutton, Captain Tuckett, Mr. Councillor Welch, Mr. A. J. Howard, Dr. Hayman, Mr. Aden Beresford, Mr. Thomson, and Mr. Colville.

Alderman Strange seconded the motion, which was agreed to.

On the motion of Councillor Dr. Sherwood, it was resolved:—That the following be appointed the Entertainments and Excursions Committee, viz.: Dr. Adams, Mr. Milton Bode, Mr. Councillor Bradford, Mr. J. P. Cockerell, Mr. Councillor Easter, Mr. Ewart, Mr. J. C. Foran, Dr. Kenneth Fraser, Mr. Councillor Hillman, Mr. Councillor Lambert, Mr. F. Lawson Lewis, Dr. MacQueen, Mr. Alderman Skinner, Mr. A. Standen Triggs, Mr. H. M. Whitley, Mr. Percy Wehner, Mr. Leatham, Dr. Merry, Mr. Jaffé, Mr. Herbert Elliott, Mr. Durlacher.

Colonel Shaw moved:—That the following be appointed the Finance Committee: Major H. P. Molineux, Mr. Councillor Simmons, Mr. Alderman Sutton, Mr. A. H. Thomas, Mr. Councillor Towner, Mr. E. E. Pratt, Dr. Bransby Roberts, Mr. Dilks, and Mr. Councillor Maude.

Colonel FitzGerald seconded, and the motion was agreed to.

On the motion of Councillor Maude, seconded by Mr. Standen Triggs, it was resolved that the gentlemen present should send in the names of suitable ladies willing to act on the Committee.

The discussion of financial arrangements concluded the meeting.

That excellent body, says the *Pall Mall Gazette*, the Coal Smoke Abatement Society, of which Sir W. B. Richmond is president, has addressed a letter to the London School Board urging it to look after its grates and stoves. A good example set by so influential an institution would, in the opinion of the C.S.A.S., have a most salutary effect. The suggestion is, therefore, that when occasion arises the Board should specify some form of apparatus that will materially reduce the evil of imperfect combustion. The Board might possibly retort that the C.S.A.S. should give point to its gentle admonition by mentioning some particular stove or stoves; but that would be considered advertisement, perhaps. The Coal Smoke Abatement Society has, at any rate, justified its existence by jogging up the School Board and other public organisations, which, as it cautiously reminds them, are amenable to the law for allowing their chimneys to emit a black and evil-smelling cloud. Its crusade against domestic chimneys is a more difficult undertaking, and its falls back upon that vague phrase, "the gradual education of public opinion." Very gradual, we fear.

THE HEALTH OF BIRMINGHAM IN 1900.

At the meeting of the Birmingham City Council on Tuesday, the Health Committee reported on the health of the city. The birth-rate for the year 1900 was 32·7 per 1000. This is a lower birth-rate than was recorded in 1897, 1898, and 1899, but a little higher than in 1893, 1894, 1895, and 1896. The death-rate was 21 per 1000, against 21·1, 19·5, and 20·5 in 1897, 1898, and 1899 respectively, and against an average of 20·4 in the previous ten years. The mortality in the first and second quarters was very high for the time of year; in the other two quarters the mortality was unusually low, with the result that the figure for the whole year is far more satisfactory than it promised to be during the first half of the year. The high mortality in the first two quarters was occasioned principally by influenza, bronchitis, and pneumonia. The zymotic death-rate was 2·7 per 1000, or 0·5 below the average in the previous five years. The deaths from measles numbered 130, or 117 below the average in the five previous years. Scarlet fever caused 2063 cases and 93 deaths. In the five previous years the average number of cases was a little higher, viz., 2171; while the deaths were almost identical in number, amounting to 92. Of the 2063 cases notified, 1827 were treated at the City Hospital.

It is pleasing to report a very large reduction in the prevalence and fatality of diphtheria, the cases falling from an average of 811 in the five previous years to 542 last year, and the deaths falling from an average of 189 to 77 last year. It is also gratifying to find that the case-mortality of this disease was very much lower than usual; only 14 per cent. of the cases proved fatal, while in previous years the mortality had ranged from 19 to 29 per cent. Whooping-cough caused 301 deaths against an average of 242 in the five previous years. The most unsatisfactory feature in the records for the year is the extensive prevalence and high mortality from typhoid fever. This disease was notified in 853 cases, against an average of 574 in the five previous years, and resulted in 179 deaths, against an average of 102. In spite of the very hot weather experienced in July, the mortality from diarrhœa was lower than usual, the deaths numbering 613, against an average of 723 in the five previous years. During the year 848 bacteriological examinations were made at the University of Birmingham, under the agreement with the Committee, in connection with diphtheria cases; 455 of the examinations made were on behalf of the Blue Coat School, where an outbreak of diphtheria occurred in the fourth quarter of the year. Three hundred and twenty-eight doses of anti-toxin were issued, two doses as a rule being sent to one patient, and the Committee believe that the very gratifying decline in the death-rate from diphtheria is due to some extent to the facilities provided by them for the anti-toxic treatment of the disease.

The erection of the new hospital in Yardley-road, which was approved by the Council in July last, is being proceeded with as quickly as possible, and immediately the new hospital is ready for the reception of any isolated case of small-pox that may occur in the city, the Committee will feel free to utilise the Little Bromwich Hospital for the reception of typhoid cases. In the meantime, as an aid towards combating the disease, they have arranged with the University of Birmingham for Widal's test to be carried out, free of charge, for patients within the city. During the year 17,832 primary visits were paid by the Women Health Inspectors, and 3929 revisits to houses needing further attention. At about 5000 houses there was sickness of some kind, and in many cases the visitors gave advice as to nursing the patients.

Under the Housing of the Working Classes, 1890, five houses have been closed, and nineteen put into habitable condition, in addition to eighty-eight closed and thirty-four demolished under the Public Health Act, 1875. The Committee also report the purchase of about 17½ acres of land lying between Bordesley Green-road and Yardley-road for the erection of working-class dwellings. The preparation of a scheme for the laying out of the land and the erection of dwellings thereon is receiving their attention.

National Health Society.

OFFICIAL TRANSACTIONS.

It is with much satisfaction that we record the success of the National Health Society's students in the recent examination held by the Sanitary Inspectors' Examination Board. Of the candidates who presented themselves for this examination after attending the Special Lectures held by the Society, not one failed to obtain the certificate of the Board. This is a great encouragement to the committee and lecturers of the Society, who spare no trouble in the arrangement of the lectures and in the individual care and teaching given to each student. The names of the successful candidates are as follows: — Miss Georgina Bevan, Miss Irene Cox, Miss Grace Looker, Miss Lucy Spiller.

In case any ladies would care to take advantage of the next examination of the Sanitary Inspectors' Board, which will be held in May, we beg to remind them that the Society is now holding another course of training lectures. Students for this course can still be received, though no time should be lost in applying to the secretary.

Elementary Examinations.—Examinations on Nursing and First Aid have recently been held in five centres in the rural districts of Lincolnshire. Seventy candidates presented themselves in all, and of these, seven only failed to reach the required standard. The majority of these candidates are drawn entirely from the working classes, which is a great satisfaction to the Society, the primary object of the teaching given by its lady lecturers in the "Homely Talks" being to reach the uneducated and labouring classes. The examiner particularly mentions one centre as being a "model class—nearly all labourers' wives."

Readers are reminded that a course of lectures on "First Aid," by J. Cantlie, M.A., M.B., F.R.C.S., is now in progress at 53, Berners-street, on Monday afternoons at 3 p.m. The subject of the lecture on Monday next, February 11th, will be "Fractures."

The following extract from the *Bradford Observer* will be read with interest by Miss Alice Ravenhill's many friends. Miss Ravenhill, it will be remembered, is working as Inspector under the Yorkshire County Councils. Commenting on the various schemes put forward by the Technical Instruction Committee of the West Riding County Council, the *Observer* remarks, "Attention having been drawn to marked advances made in the teaching of hygiene and domestic economy in America, Miss Ravenhill, who is conducting training classes for teachers in these subjects in the West Riding, is to visit the United States and report upon the methods adopted there. The Board of Education and the Sanitary Institute will combine with the West Riding County Council in making grants towards Miss Ravenhill's expenses." This is a wise step on the part of these public bodies, who are to be congratulated on their choice of a "commissioner," and the results of Miss Ravenhill's observations will be looked for with much interest.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

FEBRUARY 7, 1901.

THE CLEANSING OF STREETS.

THE need for a more effective system of street cleansing has been forcibly impressed upon the public—in London, at all events—during the past few weeks. While agreeing in the main with our contemporary, the *Lancet*. that mud may, in many respects, be preferable to dust particles, we would infinitely prefer to see its more effectual displacement, and dispense with a blessing which, in our opinion, is very much in disguise. Effective mechanical appliances for street-cleansing purposes are, as yet, in their infancy; but we are not without hope that some system may yet be devised that will do away with a state of things which has become a scandal to, and an unedifying comment on, our vaunted civilisation. As it has been pointed out, the problem still awaiting solution is not to make clear pathways through the streets, but to clear the whole thoroughfare from pavement to pavement. So far, no means of doing this exists; the mud is simply chevied, as it were, from pillar to post. The consequence is that the foot-passenger, in seeking to avoid it in one direction, plunges into a worse quagmire in another. This condition was made painfully evident during the recent snowfalls, when it was further aggravated by the unfortunate condition of most of the principal thoroughfares. Why this particular season of the year should be chosen for the carrying out of this work is one of those anomalies in Local Government which passes understanding. In January, above all other months, it is reasonable to expect a preponderance of both snow and mud, and yet this very period is chosen as the most propitious for a universal upheaval of the streets. The difficulty of cleansing is thus aggravated beyond measure, for no machine, however well devised, could hope to grapple with thoroughfares blocked from end to end with trenches, and obstructed at all points by the *débris* extracted therefrom. Although this is only a side issue of the main question, it is a very important one; but admittedly the first thing is to determine what is the most ready and effective method of cleansing the streets under normal conditions.

The removal of snow by means of salt, which the City Authorities resort to, has been characterised as "brutal but effective." The brutality comes in where the horrible mixture is allowed, as was the case recently, to lie undisturbed for hours, and to become a serious menace to the health of pedestrians. The City Authorities are delightfully economical in this matter. They are apparently under the impression that it would be a waste of salt to remove the slush until the snow ceases. But the use of salt, which has admittedly something in its favour, should be carried out under proper conditions, and until such is the case this practice must be condemned as derogatory and indefensible.

It is quite evident that proper methods of handling snow as well as mud in our streets have yet to be evolved, and whoever is successful in finding a way out of the difficulty will gain the gratitude not only of all who have had to pass through the slough of despond in London during the past month or so, but of all who are concerned in the comfort of pedestrians in large cities the world over. The "perils" of the streets under ordinary conditions are quite plentiful enough, and when to these are added the choice of being immolated in filth or permanently disabled in health through contact with a mixture of salt and snow, we think it quite time a dictator arose

in our midst to teach our City Authorities their duty. Pending the discovery of adequate mechanical means, there is always at hand the "unemployed," only too ready for a casual job, and a more effective organisation in this direction would appear to be sadly needed. Promptitude in getting them to work would also do much to alleviate the inconvenience referred to, while for the policy of parsimony that is content to put a man here and there where fifty men are needed, there is no excuse whatever. If the provinces have anything to teach London in this matter, we hope they will come forward at the earliest possible opportunity, and we shall only be too pleased to give the methods publicity in our columns. It is, indeed, a melancholy fact that the lesson has yet to be taught.

The Treatment of Inebriates.

Medical Officers of Health, quite as much as those serving under Poor Law Unions, are anxious for some effective means to be devised for dealing with the terrible disease of inebriety which has unquestionably increased in recent years. We do not refer so much to what is called the criminal classes, but to those who are regarded as respectable and well-to-do members of the community. The causes for this are various—our national prosperity for one thing; but if the secret history of many a family could be laid open we think that the grocers' licence would have to bear a greater share of the responsibility than anything else. Many a home has been darkened through its instrumentality, and many a woman has been changed from a good housewife into little better than a drivelling idiot. It is for this class that something more must be done than was provided in the Act of two years ago. If doctors would but certify that such persons were not responsible for their actions, that they were a danger to themselves as well as to the community, then some advance might be made in stamping out the disease. Even with the thoroughly depraved and criminal inebriates the present Act can do but little. In a brief report on its working, prepared by Dr. Wynn Westcott, it is shown that during the first year's operations only eighty-two patients were received into homes—and what are these among the thousands of admittedly habitual drunkards in the United Kingdom? The work is so important that those County Councils willing to provide institutions under the Act should receive substantial help from the public funds. If this could be promised greater progress would soon be made, and an important step taken to secure a further diminution in the death-rate. One other reference in Dr. Westcott's report is of interest. Acting on the experience of the past, he foreshadows what he considers are the qualifications necessary in the officers of inebriate homes. "In all cases," he says, "we think the superintendent of the institution should be a physician and not a civilian, and he should be a doctor who has an enthusiasm for the work of curing inebriety. He should be an abstainer, and so should all his officers. The home should be in the country as far as possible from towns, to avoid the risks of drinking by the straying away of patients, and so as to provide ample agricultural and gardening work. Regular and suitable labour, and regular but varied amusements should be provided. The system of preserving good order by the bestowal of rewards is to be preferred to that of punishment for errors. The culture of the patients by a well-considered moral code will be a necessary feature of the successful mode of cure. The separation of the sexes will be necessary, but there might well be two adjacent homes, one for each sex, by which means the agricultural work of one might supplement the laundry and clothing work of the other. Small dormitories should be preferred to large wards. The mental and moral standing of the nurses and attendants should be a matter of careful selection. Lastly, these homes should be self-supporting colonies, devoted to self-improvement by means of pure air, exercise, regular work, sufficient play, good food, and healthy dwellings."

An Injudicious M.O.H.

In the last issue of *Truth* a very extraordinary letter is published. It was written by Dr. G. Vawdrey, Medical Officer of Health at Farnborough, who certainly appears to have forgotten the dignity due to his profession and office. It would appear that there is a general understanding between Army Medical Officers at Aldershot and the surrounding localities that cases of infectious disease should be notified to each other, and Surgeon-General O'Dwyer wrote to the Farnborough Council complaining that this agreement had not been carried out by Dr. Vawdrey. The latter was asked by his Council to explain, and did so in the following epistle:—"My observations on the enclosed letters of the Principal Medical Officer and the Assistant-Adjutant-General are:—(1) That as a specimen of Christmas senile buffoonery they are poor; (2) as a parody on the story of the monkey, the cat, and the chestnuts, they are transparent; (3) that the British taxpayer should pay these highly-salaried officials to perpetrate such trash is a scandal. And now for facts. Inter-notification of infectious diseases is not a duty, but essentially an act of grace, and entirely at my discretion as to what districts I notify. As a matter of fact, half an hour after I received the notification I notified, as an act of courtesy, Surgeon-Colonel Ruttledge, the Medical Officer of Health for North Camp, and the Inspector sent the letter. With the Principal Medical Officer I have, and I mean to have, nothing to do. Were it otherwise I should congratulate him on his lucky escape from a more severe punishment than exposure for his part in the late Ballahooley-Bumbledom scandal. Trying to twist the tail of the Medical Officer of Health for Farnborough is sure to be amusing, and may be instructive. Further attempts are invited." This style of official correspondence is happily rare, for it reflects no credit on its author. The health of so vast a body of men such as is gathered at Aldershot is a great responsibility, and we can

well understand the anxiety of Dr. O'Dwyer when he found out that infectious disease was in an adjoining district. It would appear that some personal jealousy or feeling exists between the two medical men; but this is no excuse for the writing of such epistles to a public body. The first qualification for a Medical Officer of Health—and, indeed for all public officers—is that he should be a gentleman, and when he ceases to act as one he shows himself unfitted for the position he occupies. Dr. Vawdrey's effusion is neither funny nor clever, and the sooner he realises this the better. If he is devoid of respect for himself, at least he might have some for the profession of which he is an honourable member.

Municipal Bakeries.

The craze for municipalisation appears to have no ending in some quarters. One of the latest fads is to establish municipal bakeries. A tract on this subject has been issued by the Fabian Society which is an illustration of how one-sided statements are put forward as proving the wisdom of certain pet proposals. A large proportion of the tract is taken from reports prepared by Drs. Waldo and Walsh, and other medical officers. They describe the horrors of the underground bakehouse, and set forth the need of reformation. With all this we thoroughly agree; but it is when the writer goes on to consider remedies that we join issue with him. To argue that because "bread is already made by several public institutions" at a comparatively small cost, therefore the municipality could supply it cheaper to the public than the baker, is very poor logic indeed. In reckoning the cost of producing bread at asylums, it would be interesting to know how much is charged for interest on capital expended in the provision of buildings and plant, how much is allowed for wear and tear of machinery, and the many other things which an ordinary business is called upon to bear before the cost of production is arrived at. Without this being done such figures are altogether fallacious and misleading. Again, there is no analogy between the supply of water, gas, or trams, and that of bread. Private enterprise can better meet the public needs in providing the latter, and we deny that there is any general demand for a change. What is needed is set forth by Dr. Waldo in his well-known book. Let us have medical inspection and registration before occupancy; uniform regulations made by a central Authority, such as the London County Council, and enforced by the Borough Councils; and the total abolition of cellar bakehouses. With these reforms properly carried out there would be but little ground for complaint, and certainly no need for enlarging the scope of municipal trading.

Birmingham Health Department.

The great Midland city has long had the character of being progressive in its sanitary administration, and also for a ready acknowledgment of the value of services rendered by its officers. Last Tuesday the City Council was invited to sustain this reputation by advancing the salaries of two of its officers. The Health Committee recommended that Mr. William Holt, superintendent of the interception department, receive an increase of £50 per annum, bringing his salary up to £500. This is by no means a princely remuneration to one who has charge of six large wharves, giving employment to 550 men. During Mr. Holt's ten years' tenure of office there has been a large increase in work of his department; but his inventive ingenuity has effected many improvements in the refuse destruction machinery of the Corporation, by which means greater efficiency has been secured. The other officer recommended for increased salary was Mr. John Parker, Inspector of Nuisances. Fifty pounds additional was also recommended in this case, bringing the total up to £400 per annum. Even this is little enough for the head of such an important department. Each year the work of a Sanitary Inspector becomes more arduous, and, whilst it may be perfectly true that he acts chiefly under the supervision of the Medical Officer of Health, it must not be forgotten that he has to make himself thoroughly conversant with the intricacies of many important Acts of Parliament, as well as take action at times in many delicate cases. In large cities and towns the head Sanitary Inspector has a very responsible position, and should be much better paid than is usually the case.

An Old Proverb Discredited.

The old proverb says that a green Yule makes a fat churchyard. It may be taken as representing the general belief of mankind. The origin of the belief can probably be traced to two sources—partly to the common feeling natural to healthy, well-clad, well-nourished people that a dry bracing atmosphere such as accompanies frosty weather is more invigorating than the mild damp weather that usually distinguishes an open winter; and partly to the idea that because frost and snow in winter are natural and seasonable, they must be more healthy than an unseasonable mildness of temperature, with storms of wind and rain. But whatever may be the causes of the belief, there is no doubt that it is not borne out by the statistics of the Registrar-General. A writer in the *Scotsman* has been at pains to analyse the returns for the winter months from 1881 to 1898, and the result is conclusively to show that "mild winters, however stormy and wet they may be, are not marked with increase in mortality-rate, rather, indeed, by fewer deaths; and that the good old-fashioned severe winters not only cause an increased mortality from diseases, such as those of the respiratory organs, which are especially liable to be initiated by cold, but also from most other possible causes, seldom connected with the evil effects of cold in the public mind." The period embraced contained five exceptionally cold spells, comprising in all twenty-one months, with an average decrease in mean temperature per month of 3·01 deg. Fah., and the total death-rate was 14·48

per 10,000 higher than the mean—11·77 being attributable to deaths from lung diseases, 0·76 to deaths from heart affections, and the rest to other causes. On the other hand, five warm spells, including twenty-two months, were recorded, with a mean excess of 2·86 deg. Fah. above the normal, and the total death-rate for this period was 13·58 per 10,000 below the mean, of which the decrease in deaths from respiratory diseases was 11·97. The writer follows out his investigation in great detail, examining the death-rates for various winters, and the effects of the rise and fall in the temperature on the deaths from the various causes of disease—pulmonary, nervous, heart, and digestive diseases. The conclusion reached by a study of the official records is that the popular belief is a fallacy, that abnormally cold periods in the winter and early spring months cause an increase in the total mortality—at least in the larger towns—and that this is especially the case with regard to the old and feeble and the very young, and those who are insufficiently nourished. The increase is most marked in connection with lung disorders, but the proportional rate is higher from almost all other causes, except from zymotic diseases, the mortality trom which varies, of course, with their incidence in epidemic form. It is to be noted, however, that "the rise in the death-rate, especially from heart, nervous, and consumptive causes, is often not so great at the time as some little time after the cold spell has been in progress or has ceased."

Japan Leads the Way.

In the January number of *Scribner's Magazine* there is an instructive article by Mr. Thomas F. Millard, which shows that in some departments at least of sanitation the Japanese are bidding fair to out-distance the nations of the West who boast an older civilisation and serve as models for the Japs. Mr. Millard accompanied the Allied forces in the march on Pekin, and he writes with the authority of one who has had a wide experience of campaigning. It is not our province to follow him in his observations on the superiority of the Japanese troops in point of military equipment, but we are interested in his remarks on their field medical corps organisation. It was far superior, in his judgment, even to that of the Indian corps, which is generally reputed the most efficient possible. The Japanese field hospitals lacked nothing required by British or German standards. They alone in the Allied Army were plentifully supplied with ice, which was a most necessary adjunct in a march in which hundreds of men were daily prostrated by the heat. In the heat encountered on the march, the water-supply was an all-important consideration, for it was impossible for the troops to drink from the Chinese waterways, which are simply open sewers. Though this difficulty was foreseen before the commencement of the campaign, the Japanese was the only division of the Army adequately provided for it. They alone of all the troops carried portable filters for use in the field, their water was generally aërated, and for the officers and wounded there was a plentiful supply of bottled mineral water. All these points, in addition to the natural advantages enjoyed by the Japanese in their capacity to stand the climate, told in their favour to such an extent that on reaching Pekin only 5 per cent. of their men were unfit for duty, while 33 per cent. of the Americans were in hospital. The progressiveness and aptitude to learn of this remarkable little nation are truly making them in every department the wonder of the West.

Small-pox Ravages in Glasgow.

The prevalence of the epidemic of small-pox in Glasgow is causing the Sanitary Department considerable uneasiness. It has assumed most alarming proportions, and though meantime confined to the Eastern districts of the city, the habitation of the poorer classes, there are indications that it is about to extend to other districts. A recent diminution in the number of admissions to hospital encouraged the Sanitary Authorities to believe that the epidemic was on the wane, but their anxiety shows as yet little abatement, and they are putting forth the most strenuous efforts to cope with the disease. Dr. Chalmers, the Medical Officer of Health, in a circular to all the medical practitioners in the city, describes the present outbreak as the most severe which has been experienced since 1873. He has issued a window-card to the profession, bearing the words, "Free re-vaccination within," the doctors having been authorised to re-vaccinate all who may apply to them. The Health Committee have further authorised doctors to go to the public warehouses to offer to vaccinate the employés, and the police clerk has also issued a circular urging on the citizens the necessity of immediate re-vaccination. Very few young children have suffered from the epidemic, as the recent date of their vaccination has protected them from infection. Last summer the Health Authorities had reason to complain of the indifferent response their offers of re-vaccination met with; but there is no complaint of indifference now, for the public is, on the contrary, thoroughly alarmed, and there is difficulty in satisfying the demand for re-vaccination with the amount of lymph at present at the disposal of the Corporation.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

It may be taken for granted, whatever enthusiasts—infatuated by some pet scheme—may say to the contrary, that so long as covered sewers exist for the conveyance of sewage so long will the so-called "sewer-gas" trouble exist. Effete organic matter of which sewage is composed cannot be prevented—except at an inordinate and extravagant cost in disinfection—from putrefying and becoming malodorous. Engineers may by the construction of self-cleansing sewers, by regular flushing, and the provision of proper means of ventilation, reduce the generation, and also the offensiveness of sewer gas to a minimum, but a complete "remedy"

is as impossible as the successful discovery of "perpetual motion," or the resuscitation of the Dodo.

THE present trend of opinion among municipal engineers of experience is decidedly in favour of closing all street-surface manhole covers and substituting tall ventilating shafts. The distance apart of such shafts has been capriciously fixed at 120 yards, and the area of such shafts to be not less than 28·27in., which represents the sectional area of a 6in. circular pipe. There does not appear to be any basis established to assist the engineer in determining the relationship which should subsist between the volume of sewer gas or diameter of the sewer, and the number and sectional area of ventilators to be provided. Whether this is such a mode of deduction which is consonant with the profession of engineers is a matter on which there must be considerable doubt. It has, however, been found in practice by a number of engineers that this empirical rule is convenient. There is no evidence that it is a proper one, or that double this number of ventilators would be more suitable. Sufficient, however, for their purpose is it for copyists to follow the lead given by others, and I doubt not that the method will prevail so long as there is no absolute proof of its insufficiency or it is prohibited, as regards new schemes, by the Local Government Board.

THERE are, however, some earnest sanitarians who urge against ventilation by tall shafts that the liberation of sewer gas around the roofs of houses is dangerous, and that the prevalence of infectious disease is directly or indirectly caused by such a system. Unfortunately, opinions of adherents to each system are not supported by any facts or investigations which can carry weight with the impartial. And it is just this absence of accurate investigation and experiment which is wanting.

THE subject is one which demands the most careful study of engineers and medical men who are trained to accuracy of observation and deduction, and experiments should be conducted on the lines which I have indicated, either by engineers and medical men working for their own Authorities, or by some responsible body such as the Sanitary Institute, or the Municipal Engineers' Association, or by such Authorities as the County Councils of London or our larger cities, and it is earnestly to be hoped that these will be carried out.

CORRELATED with the subject is the ventilation of house drains. It has become with some engineers a crotchet to decry the necessity of intercepting traps on house drains, and to advocate the free ventilation of sewers by means of private drains. The chief arguments of this new school are that the intercepting trap is a minature cesspool, and that if it be abolished the sewers can be effectually ventilated by means of the house drains alone. The former argument is deserving of the same consideration that should be given to a proposal to abolish the ordinary trapped gully under waste pipes, because to form a barrier against the passage of sewer gas a water seal must be formed. If intercepting traps of too large an area or of improper form are allowed to be inserted this is the fault of the engineer himself, but under every-day conditions it is indubitable that in any household the water in an intercepting trap must be changed dozens of times daily, and that the likeness of condition of such traps to a cesspool is chimerical and foolish in the extreme.

As to the proposition for the free ventilation of sewers by means of house drains, this is not an unselfish method of transferring the obligations and difficulties from the engineer to the shoulders of the householder. That it would mean the transmission of disease from one house to another and over a whole town by the conveyance of pathogenic germs through the untrapped sewers and house drains appears to have been unobserved, and no responsible engineer should light-heartedly disregard the danger which a neglect of the obvious precaution to enforce the disconnection of house drains from sewers would produce.

I HAVE recently come across several instances where Local Authorities have incurred extraordinary expenses in repairing their highways in consequence of extraordinary traffic passing along the same by contractors and builders. It may be useful to many of my readers to learn that agreements as to compensation are very commonly arrived at on the basis of amounts varying from 1½d. to 2½d. per ton of weight carried per mile. There are many surveyors whom I have met who were unaware that they were able to recover such compensation for damage to roads caused by excessive traffic or unreasonable user, and it is therefore advisable that I should direct their attention to the provisions of Section 23 of the Highways and Locomotives Amendment Act, 1878, and Section 12 of the Locomotives Act, 1898. The object of these sections, as pointed out by the Local Government Board, is to enable "highway parishes to recoup the excessive expenditure not unfrequently occasioned by extraordinary and exceptionally heavy traffic arising from building and similar operations of a temporary character, and from other causes by which the road accommodation provided for all alike at the public expense is sometimes abused by individuals for private purposes."

THERE are many of my readers who have to design abattoirs for their Authorities, and on this account it is necessary that they should be acquainted with the best fitments and automatic gear suitable for such buildings. It is for this reason that I advise them to obtain the catalogue of Messrs. Lockerbie and Wilkinson, Ltd, whose head office is Station-street, Birmingham. This catalogue contains illustrations not only of such appliances, but of a large class of materials which are essential to the municipal engineer, as locks, partition fittings, fanlight stays and gearing, acetylene generators, and artistic brasswork, and general ironmongery, and I may also say it is one of the most beautifully got up catalogues I have seen for some time. SENEX.

NEW WATER SUPPLY REGULATIONS.

ON Monday last a conference of representatives of the Corporation, the County Council, the City of Westminster, and the London Borough Councils was held at the County Hall, Spring-gardens, for the purpose of considering the proposed amended regulations of the metropolitan water companies.

Mr. W. H. DICKINSON, chairman of the County Council, presided, and, in opening the proceedings, said the proposed regulations seriously affected the householders and owners of house property. They, as a Council, had taken examples of houses, so that the actual cost of carrying the regulations into effect, for instance, in a house of the rateable value of £45, would be £53. In another house, in which there were not so many alterations needed, and which was rated at £250, the expenditure necessary would be £85, and if it had not been of modern construction, with a proper cistern, the expenditure would have been £123, but it was a more serious question in regard to working-class dwellings. The Council was building a block of artisans' dwellings, and if these were constructed under the old regulations the cost would have been £60 for water fittings. Under the new regulations, if adopted, the cost would be £125. If this kind of thing were to operate all over London the position of London was one of great seriousness.

The conference proceeded to the discussion of the

regulations in detail. The cistern system was generally condemned, but the conference passed a resolution to the effect that, while agreeing that storage cisterns were necessary to ensure customers against temporary stoppage of supply, and that such cisterns should be properly designed for storage of water, they were of opinion that the character of the cisterns was a vital public health question, upon which public opinion stood in much need of guidance. It was suggested that the London County Council should take such steps as it might deem expedient for holding a public competition of the various improved cisterns now in the market, and to make suitable awards of merit thereon.

A resolution was also passed in favour of three-gallon cisterns as against two-gallon cisterns, as was also a motion that no apparatus capable of discharging automatically should be fixed except where water was supplied by measure, or by special agreement in writing, and in the event of refusal by the company there should be an appeal to the local Sanitary Authority, whose decision should be final. It was decided to ask the London County Council to take the necessary steps to procure the adoption of the amendments made by the conference in the proposed regulations. Although several representatives said that their Borough Councils intended to be represented by counsel at the inquiry by the Board of Trade next Monday, to support the County Council, the hope was generally expressed that each of the Borough Councils would be separately represented by counsel to show that the County Council were not alone in opposing the proposed regulations. In the event of the alterations as suggested by the companies being carried into effect, the conference agreed that the cost should be defrayed by the companies.

THE SOCIETY OF ENGINEERS.

The first ordinary meeting of the Society of Engineers for this year was held on Monday evening, at the Royal United Service Institution, Whitehall. Mr. Henry O'Connor, president for last year, in the first instance occupied the chair, and presented the premiums awarded for papers read during his term of office. Mr. Charles Mason, president-elect for 1901, was then introduced by his predecessor, and took the chair, Mr. O'Connor being the recipient of a hearty vote of thanks upon his retirement.

Resolutions of sympathy and condolence with the King and Queen and other members of the Royal Family upon the death of Queen Victoria, and expressive of loyalty to the Throne, having been unanimously adopted,

Mr. Mason, in his inaugural address, spoke of the work of a municipal engineer, especially in large towns, and he expressed surprise that more headway had not been made with the adoption of a scheme of subways for London, as the few now existing were frequently too small for the purposes they were intended to serve. He described an ideal subway occupying the entire width of the street, and said that although the cost and difficulties of construction would be great, if some scheme of rental based upon the expenses incurred in continually opening up and making good the street surfaces were arrived at, and devoted to the payment of interest on capital, a good return would result. Touching on the subject of cremation, he observed that it was worthy the special study of those interested in municipal engineering as a system which was likely to be introduced generally in the near future. He predicted that before the middle of the present century every town and borough in the coutry would have a crematorium as part of its general equipment. In regard to the science of heating and ventilation, the small extent to which well-known and efficient systems of heating had been adopted in private houses was due chiefly to old associations as to the hearth and to cheap fuel. There were advantages and disadvantages in warming by steam, hot water, and hot air, and it was impossible to adapt the same principle to all buildings. He urged the necessity of attending to the smallest details of construction in each case, as the circulation of hot water was very easily adversely affected. He discouraged heating by high-pressure water and hot-air stoves for domestic work. Ventilation was closely allied to, and dependent upon, heating; the introduction of an ample supply of pure fresh air being the main consideration in arranging any system (whether natural or mechanical), without allowing such air to become overheated or to cause draughts on its admission into the apartment. Want of attention to an apparatus after it had been installed was the chief cause of inefficient working, and very often the engineer received the blame which should be bestowed on the caretaker. As in the case of heating, however, it was impossible to adopt the same principle for all buildings.

A vote of thanks to the president closed the proceedings.

Public Works.

SEWERAGE.

The Narberth Rural District Council has adopted plans for the sewerage of Saundersfoot.

The Urban District Council of Haywards Heath is acquiring a site for works of sewage disposal.

The West Penrith Council has decided to advertise for tenders for carrying out the Marazion sewerage scheme.

The East Ham Urban District Council has received the sanction of the Local Government Board to the borrowing of £2460 for sewer ventilation, repayable in thirty years.

At the last monthly meeting of the Portslade and Southwick Outfall Sewage Board, the clerk read a letter from the Local Government Board relative to the application for sanction to raise £3700 to complete the works, and asking for further information and plans.

A Local Government Board inquiry was held at Enfield recently for the purpose of receiving the application of the Edmonton District Council for loans of £9550 for works of sewerage and surface water drainage, £8312 for works of street improvements, £3740 for works of sewage disposal, £850 for the provision of hydrants, and £500 for the purchase of a steam roller.

The Radstock Urban District Council, near Bath, is threatened with proceedings by the Somersetshire County Council for polluting the watercourse running through the town, and has now unanimously decided to instruct Messrs. D. Balfour and Son, of London and Newcastle, to prepare a scheme of main sewerage and sewage disposal to submit to the Local Government Board for its approval.

The Sewage Committee of the Gorton District Council last week recommended that application be made to the Local Government Board for sanction to borrow £17,000 for the purpose of further sewerage and sewage disposal works within the district. The Committee also recommended that application be made to borrow £2750 to carry out certain works of surface water drainage in the district, and a further £3000 to cover the cost of additional works of sewerage and sewage disposal already carried out.

The Watford Urban District Council proposes spending about £20,000 in works of sewerage, water supply, and street paving.

The Bournemouth Town Council has decided to make application to the Local Government Board for sanction to a loan of £2000 for carrying out certain drainage works.

The Joint Committee of the Brampton and Haltwhistle Rural District Councils has instructed Mr. Harry W. Taylor, A.M.I.C.E., of Newcastle-on-Tyne and Birmingham, to prepare schemes of sewerage and water supply for Gilsland.

The Shipley District Company has resolved that application be made to the Local Government Board for sanction to borrow £30,000 for drainage and sewage treatment purposes, in addition to all sums already sanctioned for such purposes.

At the last monthly meeting of the Belper Urban Authority a communication was received from the Local Government Board with reference to the sewerage scheme, which is being undertaken at a cost of £40,000. Some modification has been made in the original scheme, but to this the department offered objection, and the work will be delayed. Mr. Jones said it had taken six years to reach the present stage, and they had done admirably to prevent the heavy expenditure.

Mr. Carter, C.E., Edinburgh, has made another report on the disposal of the Dumfries sewage. He virtually pronounces impracticable the schemes for conveying the sewage of Dumfries and Maxwelltown to the sea; points out important difficulties in the way of treating it by joint-works on the Maxwelltown side, which might otherwise be economically advantageous to Dumfries; and indicates his adherence to the scheme which he originally submitted, with the possible substitution of a field on Castledykes property for Kingholm as the site of the purification works.

An important Local Government Board inquiry was held at Greetland, last week by Mr. E. A. Sandford Fawcett. The West Riding Rivers Board had applied to the Local Government Board for consent to take proceedings against the Greetland Dyeworks Company, Greetland, in respect of offences alleged to have been committed against the West Riding of Yorkshire Rivers Act, 1894, and the Local Government Board had directed an inquiry into the subject matter of the application. After some discussion the Inspector said the Rivers Board was willing to forego the prosecution provided that if the land was not secured from Lord Mexborough the company would proceed to lay down the works in June on other land. The inquiry then adjourned, and the Inspector subsequently visited the dyeworks.

Few, perhaps, have any adequate idea, says the *City Press*, of the magnitude of the main drainage system of London, a system that was founded by the late Metropolitan Board of Works on the lines laid down by Sir Joseph Bazalgette, and has since been greatly extended by the London County Council. What the responsibilities of the Council in this direction are may be judged from the figures given this week with reference to the quantity of sewage dealt with last year. It seems that altogether no less a quantity than 84,609,000,000 gallons was treated, this representing an advance of 6,929,186,000 gallons compared with the output of the previous twelvemonth. What the total will be when the population of London grows to double or treble what it is at present it surpasses one's powers of calculation to imagine. Already, owing to the strain on the existing works, the Council has been obliged to enter into a contract for the expenditure of close upon a million sterling upon the enlargement of the outfall.

Last week, Colonel Steele, an Inspector from the Local Government Board, held an inquiry at Doncaster, as to the proposed sewage schemes for Askern, Bawtry, and Bentley.

Sanction has been obtained by the Wortley Council to the borrowing of £12,700 for purposes of sewerage and sewage-disposal works in the Chapeltown special drainage district.

The Mutford District Council has passed the following resolution:—"That application be made to the Local Government Board for sanction to borrow a further sum sufficient to cover the cost of the sewerage scheme at Kessingland and the incidental expenses, it having been found, after twice advertising for tenders, that the work cannot be carried out within the limits of the loan already sanctioned."

Mr. R. H. Bicknell, M.I.C.E., held an inquiry at the District Council Offices, Drighlington, last week, on behalf of the Local Government Board, with respect to a petition for a Provisional Order empowering the Council to put in force the powers of the Land Clauses Act with reference to certain lands required by them in the parish of Tong for purposes of sewage disposal. Mr. Walter Beverley supported the application of the District Council, and said the works of sewage disposal had formed the subject of three or four inquiries previously. The District Council now proposed to construct the work on a site just outside the township, situate in Tong, and belonging to Sir Robert Tempest. The site consisted of a little over six acres, and the estimated cost of the works of sewerage and sewage disposal was £12,600. Mr. Bairstow opposed the application on behalf of Sir Robert Tempest on the ground that there was no right of cart road to the site, and that the construction of sewage works there would interfere with Sir Robert's sporting rights. Evidence was given on each side.

WATER.

The Tamworth Town Council is requiring lands for waterworks.

It is understood that Mr. Baxter, C.E., Dundee, has been asked to state how long the present pipes from Loch Benachally will serve their purpose, also to suggest in what way Rattray may have an ample supply of water.

The Examiners of Standing Orders of the House of Commons certify that the standing orders applicable to the Southport Waterworks (Transfer) Bill, the Bury Corporation Bill, and the Bury Corporation Tramways Bill have been complied with by the promoters.

An adjourned meeting of the Littlehampton Urban District Council was held last week for the purpose of receiving tenders for water mains in connection with the new water supply for the town. The tender of Messrs. Nunn and Co., Tenderden, for constructing water mains at Crossbush, at £2410, was unanimously accepted.

The Torquay Town Council held a special meeting last week, and passed a resolution extending the time for Teignmouth District Council to exercise the option offered to take a supplementary water supply from the Torquay waterworks. Teignmouth wrote that they were considering various schemes for augmenting their supply, and had been unable to come to any decision. It was agreed to extend the option one month from the 20th ult. Afterwards the Council went into committee to discuss the financial position of the Corporation, especially the arrangement with the bankers respecting the temporary loan of £60,000 for the purchase of the watershed and the prospect of floating a new loan for £100,000, on which question the Mayor and the Town Clerk visited London recently.

The Joint Committee of the Brampton and Haltwhistle Rural District Councils has instructed Mr. Harry W. Taylor, A.M.I.C.E., of Newcastle-on-Tyne and Birmingham, to prepare schemes of water supply and sewerage for Gilsland.

At the last monthly meeting of the Hayfield and Mellon Rural District Council on the question of the Stockport Corporation Water Bill, which materially affected the district, it was agreed to consult Mr. Hodgson, engineer, and also to instruct the Clerk to draw up the necessary petition required for offering formal opposition to the Water Bill if required, and employ counsel.

The Cromer Water Bill came last week before Mr. Jeune, one of the Examiners of the House of Commons, for proof of compliance with the preliminary Standing Orders relating to private Bill legislation. There was no opposition at this stage, and the necessary formal proofs having been given, the Examiner decided that the Standing Orders had been duly complied with. The Bill will accordingly be reported in due course for first reading.

The Stratton and Bude Water Supply Bill having been declared to be in compliance with the Standing Orders of Parliament, the Urban District Council has passed the following resolution:—"That the Council do confirm the propriety of the promotion of a Bill in the ensuing session of Parliament to authorise the Council to purchase the undertaking of the Bude Harbour and Canal Company, and to confer powers on the Council with respect to local government and water supply, and for other purposes."

The report and statement of accounts of the directors of the Cleveland Water Company for the past half-year states that after providing for all expenditure there remains a balance of £5044 4s. 1d. This sum enables the directors to recommend that a dividend at the rate of £9 10s. per cent. per annum on the "Original" and "A" shares, and £6 13s. per cent. per annum on the "B" shares (free of income tax), be declared payable on and after the 14th inst., and that £125 be reserved for contingencies. This will absorb £3355, and leave a balance of £1689 4s. 1d. to be carried to the credit of next half-year's account.

Meetings have been held at Stainforth, Hatfield, and Hatfield Woodhouse to protest against the expense of the scheme foreshadowed by the County Council. General satisfaction with the present supply has been unanimous. If the villages are ultimately compelled to have recourse to a fresh source of supply, each of them seems determined to have nothing to do with Thorne. The District Council does not expect to have the views and estimates of the engineer for consideration until after the election, when the demands of the County Council will be brought prominently before the ratepayers.

At Denbigh County-court last week, Mr. E. Roberts, solicitor, applied to Judge Sir Horatio Lloyd to enter judgment for the Denbigh Water Company against the Denbigh Town Council for damage done by the steam roller and for an injunction against its further use, or in lieu of this that he grant a new trial. At the last Court the Judge gave judgment for damage done to all pipes more than 18in. deep, and granted an injunction; but after reading a full report of the trial, and seeing that the company had practically waived the injunction, he wrote to the Registrar, withdrawing the injunction. Mr. Ralph Bankes, barrister, on behalf of the Corporation, resisted the present application, contending that the Judge's view as to the company's waiving the injunction was correct, and that there were no new facts justifying a new trial. The Judge refused the company's applications, and gave the costs of the day to the Corporation, including counsel's fee.

At a recent meeting of the St. Germans District Council with reference to the reply to be forwarded to the Local Government Board, giving particulars of the amount of money spent in connection with the Downderry water supply, the deputy Clerk stated that the total sum was £1848.

We understand that it is still the intention of Kelso Town Council to carry out its scheme for taking a supply of water from the sources on Ladyrig farm—this time, however, for the requirements of Maxwellheugh alone—and that, with this object in view, the Council has made approaches to the parties interested in order that an arrangement may be come to.

A public meeting of the owners and ratepayers of New Mills was held last week for the purpose of expressing by resolution consent to the opposition by the Urban District Council of the Stockport Corporation Water Bill, now in Parliament, which seeks to take the waters of Kinder and construct waterworks there. A resolution was passed, on the motion of the Chairman, giving consent to such opposition, and to the cost of the same being paid out of the district rate.

LIGHTING.

The price of gas at Hull is to be reduced from 2s. 10d. to 2s. 8d. per 1000ft.

The Belper District Council has decided to oppose the Derbyshire and Notts Electric Power Bill.

The Cleckheaton Urban District Council proposes a loan of £25,000 for electric lighting and refuse destructor purposes.

The laying down of additional electric cables is to be undertaken by the Corporation of Newcastle-on-Tyne at a cost of £10,000.

The Arbroath Gas Corporation, as Electric Lighting Committee, has agreed to recommend to the Town Council that the Council should undertake the installation instead of a private company.

With a view to a greater demand, the Electricity Committee of the Islington Borough Council recommends that, at the expiration of the present quarter, the price for electrical current during the hours of daylight be reduced from 3½d. to 2d. per unit.

We understand that a company has been negotiating with a property owner in the town of Brentwood to acquire land upon which to erect an electric lighting station. If such were established it might prove beneficial to the lighting of the town, which has not been invariably satisfactory.

The half-yearly report of the Gaslight and Coke Company shows that after providing for the fixed charges there remains a balance available for distribution of £551,753, out of which the directors recommend a dividend on the ordinary stock at the statutory rate of £4 8s. per cent. per annum, carrying forward the sum of £221,570.

A special meeting of the Cromer Urban District Council was held last week, when the business was to consider a report from the Highway Committee in reference to the purchase of a site for an electric lighting station and store yard. Mr. F. W. H. Keith, on behalf of the Bond Cabbell Trustees, offered an acre of ground on the Beach Station-road for £800, to include road-making, the Council to agree in the diversion of a footpath running through the property, and also to a stipulation that no burning of material should be allowed upon the site. On the motion of Mr. H. Broadhurst, M.P., seconded by Mr. H. Rust, it was decided to accept the offer, on the condition that the stipulation as to the burning of material was struck out. It was stated that the original price asked for the land was £1370.

THE Middlesex County Council has resolved to oppose the application of the Friern District Council for an Electric Lighting Order unless clauses for the protection of the Council are inserted.

MESSRS. CLAUD HAMILTON, LIMITED, have secured the contract to fit up the necessary appliances required for the electric lighting of the concert hall and principal restaurant at the Glasgow International Exhibition.

THE Walsingham District Council has granted the application of the Parish Council of Fakenham for leave to break up streets and roads under the jurisdiction of the District Council for the purpose of laying on the mains for lighting the town with electricity if the town should sanction the scheme which would shortly be laid before the ratepayers.

AT the last monthly meeting of the Newark Urban Authority, the Electric Lighting Committee reported that it had considered the two schemes for electric works for the borough, submitted by Mr. Vesey Brown, and had resolved to recommend the Council to adopt the larger of the two schemes at an estimated cost not exceeding £30,000, and that application should be made to the Local Government Board for sanction to a loan of £30,000 for the purpose, and that on such sanction being obtained the purchase of the sites in Water-lane from Mr. B. Chatterton and Miss Handley should be proceeded with. The confirmation of the report was agreed to, only one voting against it.

A PROPOSAL is before the Ramsgate Corporation for the construction of a tunnel from the harbour to the gasworks, a distance of about three-quarters of a mile, for the conveyance of coal and other material to and from the gasworks. The question of supplying the borough with electricity, under the recent Order obtained by the Corporation, was discussed with some warmth at a recent Council meeting, and ultimately it was decided to invite tenders for laying the connecting cable for the supply of electricity within the compulsory area, and also to approach the Thanet Light Railway Company to ascertain on what terms they would be prepared to supply electric current in bulk. The last-named proposal met with strenuous opposition from the Chairman of the Committee and other members, who urged that the Corporation should retain all the powers obtained under its Order in its own hands. It is intended to use electricity as the motive power for the tunnel already referred to.

COLONEL LUARD held an inquiry at Llandudno last Thursday on behalf of the Local Government Board with reference to an application by the Council for power to borrow £1500 for purposes of electric lighting. Mr. A. H. Preece, the consulting electrical engineer to the town, with whom was Mr. C. H. Morton, the resident engineer, stated that it was proposed to extend the steam condenser at a cost of £1126; building work was to be carried out at a cost of £87; and for engineering expenses and contingencies £287 was estimated. The balance of the borrowing powers applied for was for future outlay in duplicating the armature of the circulating pump which supplies the condensers, a new pump being also provided for. A portion of the engineering expenses is due to the putting in of a new air pump, which is to take the place of that supplied by the contractor for the works, who is taking it back in exchange for the larger apparatus, free of cost. A wooden louvre arrangement is to be erected on the south and west sides of the works to keep the rain from the condenser.

GENERAL.

THE Woolwich Borough Council has obtained a loan of £6550 from the London County Council for the erection of stables and the construction of an underground convenience.

THE Southport Urban District Council is requiring land for hospital purposes.

THE London County Council has decided to lend £2430 to the Shoreditch Borough Council for street improvements.

THE Provisional Orders applied for by the City Council of Leeds and the Urban Council of Prescot are for the clearance of insanitary areas.

A LOCAL Government Board inquiry has been held at New Brompton into the application of the Urban District Council for sanction to a loan of £3400 for private street works.

THE Health Committee of the Thirsk Council recommended the City Council, at its meeting last Monday, to take the public baths in St. George's Field under its own control, the lease under which they are let to Mr. Shepherd expiring on February 4th.

A CABLE between Porthcurnow, Cornwall, and St. Vincent, Cape Verde Islands, by way of Madeira, was according to a notification from the Eastern Telegraph Company, opened for traffic on Wednesday in last week thus completing the new direct cable route betwee Great Britain and South Africa.

AN inquiry was held at Bexhill last week respecting the application of the Bexhill Urban District Council for sanction to utilise certain land acquired at Clinch Green as a site for an infectious diseases hospital. The opinion was expressed that the site was a very suitable one, and there being no opposition, the inquiry closed.

MR. W. H. WALKER, the receiver for the debenture holders in the Isle of Man Tramways Company, has filed his accounts for the term between 25th July and 31st December last. The gross receipts were £29,820. Out of this was paid in working expenses and interest on debentures £23,861, leaving a balance of £5958, which is now paid into Court, available for creditors and shareholders.

THE minutes of the Parks and Cemetery Committee of the Gorton District Council last week asked the Council to sanction the borrowing of a further sum of £15,000 for the completion of the whole of the cemetery. Mr. H. Dean, in moving its adoption, said the Council had already borrowed £15,704, and the £15,000 it was now proposed to borrow would make up the full loan sanctioned by the Local Government Board of £30,704 as the total cost of the cemetery. The recommendation was adopted.

THE usual meeting of the Sub-committee of Edinburgh Town Council on the cable tramways took place last week, and steps were taken to push on the Portobello line as quickly as possible. The contractors maintain that they will have the line open and carrying traffic by the summer-time, but the Committee has its doubts as to whether this is possible. Another point discussed was the carrying of the cables at the foot of the Mound. At this point there is a large tunnel in which Water Trust pipes, &c., are carried, and it has been arranged that the pulleys on which the cable will run will be fixed to the top of the tunnel.

THE total number of cases of small-pox in Belvidere Hospital, Glasgow, at the end of last week was 386. A great number of persons are being re-vaccinated. Two cases from Shawlands and Crossmyloof of a mild nature have been removed to Belvidere Hospital. There have also been cases from Crosshill and Pollokshields. A rumour that a number of the city car conductors had been affected has been contradicted by the manager, who states that not a single official has been off duty with small-pox. Special arrangements made last year for re-vaccinating the whole of the staff were largely taken advantage of. The cars are thoroughly cleansed and disinfected every night, and every precaution is being taken to prevent the disease spreading.

The Ashford Urban District Council is acquiring a site for an isolation hospital.

The Metropolitan Borough Council of Bethnal Green requires land for an electric generating station and refuse destructor.

The Middlesbrough Town Council has decided to apply to the Local Government Board for sanction to a loan of £2500 for street works.

The Grimsby Sanitary Committee has decided to recommend the Town Council to undertake the removal of household refuse instead of getting the work done by contract as hitherto. It is suggested that a destructor be built at each end of the town to consume the combustible refuse, and the expenditure is estimated at £4400.

To such an extent has the epidemic of measles, which broke out in the first week of January, spread in the south-west of Mull, that there are now no less than 120 cases being attended in the Ross district of Mull by Drs. MacKechnie and MacNab. In Bunessan there are 40 cases. The schools of Iona, Creich, and Bunessan are closed.

Annual Reports Received.—Maldon Rural Sanitary District (M.O.H.), Borough of Stalybridge (M.O.H.), Kettering Urban District Council (M.O.H. and Sanitary Inspector).

PERSONAL.

Dr. Broster has been reappointed Medical Officer for Wirksworth.

Mr. John W. Davies has been appointed Surveyor for the Holywell urban district.

The Romsey Town Council has increased the salary of Mr. Jenvey, Borough Surveyor, by £20 per annum.

The salary of Dr. Pilkington as Medical Officer of Health for Preston has been increased from £450 to £550 per annum.

Mr. J. Veit, Assistant Borough Surveyor for Barrow-in-Furness, has been appointed Surveyor for the Goole urban district.

Dr. T. Martin has been appointed Medical Officer and Public Vaccinator for the third district of Newbury, in room of Dr. Lambert.

Mr. James Morris, Inspector of Nuisances for Hanley, has been appointed Inspector of Nuisances and Surveyor for the rural district of Docking, Norfolk.

Mr. Charles Broun, Burgh Surveyor, Airdrie, has been appointed Burgh Surveyor and Sanitary Inspector for the burgh of Hawick, at a salary of £210 per annum.

Dr. Sheppard has been reappointed Medical Officer of Health for New Forest rural district, at an annual salary of £300, subject to the approval of the Local Government Board.

We congratulate Dr. Allan, late Medical Officer of Health to the Strand Vestry, on his appointment as Medical Officer of Health to the city of Westminster. The salary is £800, rising to £1000.

At a meeting of the Electricity Works Committee of Lincoln Corporation last week, Mr. C. S. Vesey Brown, the Electrical Engineer, tendered his resignation, which was accepted. Mr. Vesey Brown, who is leaving to take the position of General Manager to the Northern Counties Electricity Supply Company, Limited, Newcastle-upon-Tyne, came to Lincoln about five years ago to superintend the installation of electric lighting for the city, and under his direction the supply has been developed most satisfactorily.

Dr. C. H. Conolly has been reappointed Medical Officer of Health for Wood Green, subject to the approval of the Local Government Board, at a salary of £100 per annum.

Dr. Karl C. Gimson, M.B., B.C. (Cantab), has been appointed by the Metropolitan Asylums Board for one year as the Medical Officer of Bridge School, on the terms and with the duties already approved by the Board.

Mr. C. S. Vesey Brown has resigned his position as Electrical Engineer to the Lincoln Corporation, in order to take up the appointment of general manager to an electricity supply company in Newcastle-on-Tyne.

The Brighton Corporation has decided to increase the salary of Mr. Johnston, the Waterworks Engineer, from £650 to £900 a year, Mr. Johnston having agreed to remain in the service of the Corporation for at least another five years.

The Local Government Board has written the Tyne Port Sanitary Authority confirming the appointment of Dr. Harker as Medical Officer for the year, but urging the Authority to consider the advisability of having an officer to devote the whole of his time to the work.

Mr. John R. Douglas, who for the past four years has acted as county Road Surveyor of Nairn, has accepted an appointment as Road Surveyor in the Colony of the Gold Coast, Western Africa. Mr. Douglas has tendered his resignation to the Road Board, and will leave for West Africa within a month.

Miss Marie Stewart, of London, was last Monday appointed by the Leeds Corporation a Sanitary Inspector for the city. The lady succeeds in the office Miss Hobson, who has resigned. The new Inspector was educated at Girton, and has been studying medicine. The post was sought for by about a dozen ladies.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

The following meetings will be held on Wednesday, February 13th, 1901 :—

Examination and Literary Committee, at 3 p.m.
General Purposes and Finance Committee, at 4 p.m.
Election Committee, at 5.15 p.m.
Members' Sessional Meeting, at 7 p.m.

LAW CASES.

A Question of Closets.

At Newton Abbot Petty Sessions Mr. Hamlyn, of the Clay Cutters' Arms, Chudleigh Knighton, was summoned by the Newton Abbot Rural District Council, as the Sanitary Authority, for committing two breaches of the bye-laws in respect of the erection of buildings at Kingsteignton, and allowing the same to be occupied without certificates from the Council for occupation. Mr. Horner, Clerk to the Rural Council, prosecuted, and Mr. J. Hutchings defended.

Mr. Horner said that the bye-law in question had been approved by the Local Government Board, and distinctly stated that plans of various buildings about to be erected must be submitted to the Council for approval, and if passed the building must be erected in accordance with those plans. In March of last year plans were submitted on behalf of Mr. Hamlyn for the consideration of the Council by Mr. Segar, architect, of Newton Abbot. They were approved, the plans showing that earth-closets were to be provided

some 54ft. from the dwelling-houses. In August Mr. Rogers, Sanitary Inspector, reported to the Rural Council that he had received an application from Mr. Hamlyn for the Council to extend their sewer to the cottages. The Council then stated that they could not accede to the request, and at the same time informed him that he must carry out the work in accordance with the plans approved by the Council. Later in the year Mr. Segar again wrote to the Council asking them to rescind their decision, but this they refused to do. In December Mr. Rogers reported to the Council that water-closets had been substituted for earth-closets, and that Mr. Hamlyn had applied for certificates for occupation of the cottages. The Council then passed a resolution that as the plans had not been complied with they were unable to grant certificates. Notwithstanding that, Mr. Hamlyn had allowed the cottages to be occupied.

Mr. Rogers, Sanitary Inspector, produced the plans approved by the Council for the erection of four cottages by Mr. Hamlyn at Chudleigh Knighton, showing that earth-closets were to be provided. The cottages were built in accordance with the plans, but earth-closets had not been provided. There was no water to be obtained within several feet of the closets.

Dr. Mapleton, Medical Officer of the district, said he had inspected the houses which were occupied. They contained ordinary hand-flushed closets, which were injurious to health. In reply to Mr. Hutchings, witness said he had never known a properly-erected earth-closet to be injurious to health. Hand-flushed closets were likely to cause disease.

Mr. Hutchings, in defence, said in the Act in question there was a section which stated that houses should not be occupied until certificates were given stating that there was ample water supply. It was evident that the Council considered there was insufficient water supply, and therefore he could not defend his client on that point in the face of the section of the bye-law. At the same time, however, he complained that the Council had not stated to his client what they really desired. He considered that the closets erected by Mr. Hamlyn were far better than those desired by the Council. About two years since the Council instructed an owner of some property near Mr. Hamlyn's houses to have closets similar to the ones his client had erected in the houses instead of the ones now desired by the Council.

Mr. Segar, architect, said he recommended that the hand-flushed closets be erected, as he considered they were more beneficial in many respects.

The Bench imposed a fine of £1 and costs in each case.

The Smoke Nuisance in Huddersfield.

At the Huddersfield Police-court, Messrs. Joseph Lumb and Sons, Limited, manufacturers, Folly Hall, were charged with having failed to obey an order from the Corporation's Sanitary Inspector to abate a smoke nuisance on eight days from September 18th to October 22nd.

Dr. E. G. Annis, Medical Officer to the Huddersfield Corporation, said seven summonses were issued against the defendant firm in October last, and were heard on the 29th of that date. The Chairman then said it was evident the firm had endeavoured to obviate the nuisance, but as they had not quite succeeded they would adjourn the case for three months. Since then the following developments had taken place. On December 19th he (Dr. Annis) received a letter from the defendants asking him to call at their premises and see the arrangement they had made for consuming smoke. He accordingly called on December 20th, and Mr. Jesse Lumb explained what alterations had been made at the boilers. He stated that they had found that the stoker did not always keep the patent doors working properly, and thereby had caused more smoke than was necessary. They had now fixed additional steam blowers to the four boiler fires, and were about to add an automatic arrangement to the patent doors, so that they would work properly without the stoker being able to alter them. In his (Dr. Annis's) presence the four boiler fires were stoked together with the new arrangements, and seemed to work satisfactorily. To Mr. Lumb he explained that in any case where they found that proper and sufficient plant had been provided by owners, and that then black smoke was emitted, they would have to proceed against the stokers themselves. The Authorities had taken several observations of this chimney since the hearing of the case, and the averages had been 6 minutes, 6½ minutes, 8 minutes, 5 minutes, and 2½ minutes, black smoke. The latter average was from December 15th to January 14th, so that it would seem that the alterations had resulted in a considerable diminution in the amount of smoke. He asked for a small penalty, with costs.

Mr. F. Sykes (Messrs. Ramsden, Sykes, and Ramsden), on behalf of the defendants, said that both since the summonses were issued and before, Messrs. Lumb had been at great trouble to prevent the emission of black smoke. They appreciated the efforts which Dr. Annis had made since October last, and they felt that he and those with whom he had to confer would in future appreciate the position in which they were placed, and that they were doing everything in their power to carry on their business with as little obnoxious element as possible. When he entered the Court that morning he understood that Dr. Annis would be satisfied with the payment of costs, and he was prepared to assent to that.

Dr. Annis said he had received a message from Messrs. Lumb that morning to the effect that they left the matter entirely in his hands.

After a little further argument, Dr. Annis consented to the payment of the costs alone, and the case was settled on those terms.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2083.—Yearly Reports of Law Cases: How Obtainable. —"J. S." writes:—"Can you please inform me where I can get the reports of cases under the Public Health Acts decided in the Queen's Bench Division in the year 1897?"

Answer.—Such cases are reported in the *Justice of the Peace*, the *Law Times* Reports, the *Law Journal* Reports, &c. We advise, however, that "The Yearly Digest of Cases" (price 15s.), which is a digest of all cases decided in the Superior Courts and reported in all the Reports, be procured. From this publication the reader may ascertain what cases are of especial interest to him, and also what publication contains a full report of the case—for no one publication reports all the cases decided.

2084. — Insanitary Workshops: Offensive Trades. — "E. C." writes:—(1) "Is it the duty of the Sanitary Authority to enforce the requirements as to reasonable temperature in workshops? (2) In a cordial manufacturer's establishment (not a factory, there being no machinery) two men are employed all day in a loft where fermentation is carried on. The windows and doors of the loft are darkened, and made almost air-tight to keep up the temperature. What powers, if any, has the Factory Inspector or the Sanitary Authority to act? (3) In a thickly-populated district there is a knacker's yard, to which is attached a chemical works. There is frequently an offensive smell from the horseflesh being boiled, and from the bones and animal refuse being 'digested.' Can the Sanitary Authority succeed, and, if so, under what powers in proceedings for having the yard closed and the business transferred to a less densely-populated district?"

Answer.—(1) No. (2) If the workshop, not being ventilated or kept in a cleanly state, or is injurious to the health of those

employed therein, it will be a nuisance under Sec. 91 of the Public Health Act, 1875, or Sec. 107 of the Public Health (Ireland) Act, 1878. (3) We presume the district referred to by the querist is in Ireland, whence his letter is addressed, although he omits to state such an important fact. If this be the case the Local Authority should institute proceedings under Sec. 130 of the Public Health (Ireland) Act, 1878.

2085.—Books on the "Times" System: Books for Workshop Inspectors.—"E. C. L." writes:—(1) "What is, or where shall I find particulars as to the *Times* system of obtaining books as referred to in reply to Query 2042 in your issue of December 21st? (2) What books containing cases decided as to outworkers, &c., would you recommend for a Factory and Workshop Inspector under the Sanitary Authority? Also (3) what book giving prices of material and work would you recommend?"

Answer.—(1) See issue of Sanitary Record for January 19th, 1900. (2) There is no publication devoted specially to the reports of such cases. Redgrave's "Factory Acts," price 6s., or Abraham and Davies' "Law Relating to Factories and Workshops," price 5s., will be found useful. (3) Lockwood's "Builders' Price-book," price 4s., and Buckingham's "Contractors' Price-book," price 5s., are recommended. Any of the books named may be obtained from the office of this journal, post free, at the prices named.

2086.—Bacterial Sewage System: Particulars.—"Surveyor" writes:—"I am about to deal with the sewage of my district, which is a mining one, sewered on the separate system, with a population of 13,000, and not likely to increase very rapidly. The privy system is in use. It is proposed to provide open septic tanks with double contact beds. I should be glad if you could advise me as to the number, capacity, and description of beds to be used and work required. The water company estimate the water supply at 10 gallons per head, but from a careful gauging of the sewer at the outfall, the flow averages only six gallons per head in twenty-four hours. In face of this will it be necessary to base my calculations on a dry-weather flow of more than 10 or 12 gallons per head? I may add that money was borrowed from the Local Government Board for sewage disposal some time ago."

Answer.—If the Local Government Board have, as stated by the querist, sanctioned a loan for the purpose of sewage disposal, this could only be done on a scheme submitted to them at the time, and approved. If this approved scheme is to be now disregarded by the Local Authority, and an entirely new scheme substituted, the cost of which is to be defrayed with the loan obtained for the original scheme, the Local Authority should obtain the approval of the Board to the same. The present requirements of the Local Government Board as to capacities of sedimentation tanks, contact beds, &c., are fully set forth in Adam's "Local Government Board's Requirements as to Sewage Disposal Schemes," price 2s. 6d., obtainable from the office of this journal, which the querist should follow. The capacities of the tanks and contact beds should be estimated on a sewage flow equivalent to 20 gallons per head, as doubtless the insanitary and filthy privy system which is in use in the district will be abolished, from both a sanitary and financial point of view, when a proper sewerage system is completed.

2087.—Colonial Sanitary Inspectorships: Vacancies.—"W. R." writes:—"Being qualified for the post of Sanitary Inspector and also Food Inspector, will you please advise as to how I could obtain a berth in South Africa, Canada, or any of the Colonies?"

Answer.—We published in our issue of September 21st last, page 263, a list of papers in South Africa in which advertisements for Sanitary Inspectors are occasionally inserted, and this should be referred to. Vacancies in Canada are advertised in Canadian journals only, and not in England. Reference should also be made to Query 1871 in our issue of July 13th last.

2088.—Food and Drugs Acts: Proof Spirit: Meaning of Term.—"Underproof" writes:—"I have a certificate from an analyst upon a sample of whiskey which states that it 'contains 8 per cent. of added water over and above that contained in 25 degrees underproof whiskey, it being a diluted whiskey of the strength of 31·3 degrees.' I shall be greatly obliged to you if you can tell me how these figures are arrived at, and what percentage of water is in whiskey which is 25 degress underproof?"

Answer.—Proof spirit is a term used to denote a mixture containing 49·24 per cent. alcohol by weight and 50·76 per cent. water, or 57·5 per cent. alcohol by volume and 42·5 per cent. water. Spirits weaker than this are described as so many degrees underproof, so that pure water would for this purpose be described as 100 degrees underproof. Whiskey described as "25 degrees underproof" means that the sample contains 75 measures of proof spirit and 25 measures of water added. Now, 75 measures proof spirit contains 43·1 measures of alcohol, therefore spirits of 25 degrees underproof would contain 56·9 per cent. water by volume. In the same way 31·3 degrees underproof means that the sample contains proof spirit 68·7 volumes and water 31·3 volumes. Now this 68·7 volumes of spirit, if it were 25 degrees underproof, would have added to it 22·9 volumes water; but it has added to it 31·3 volumes, *i.e.*, 8·4 volumes of water over and above that contained in spirits of 25 degrees underproof.

(*Continued from page* 112.)

CHAPTER XVII.—MEASUREMENT OF CURRENT.

Having briefly described the principle of the modern electric generators, motors, and transformers, we will proceed to define more clearly some of the units in which the power of a current is expressed, and which have been frequently mentioned in the foregoing chapters, as well as to describe what relation they bear to one another, and, as far as possible in a simple manner, how they are measured, and what their equivalents are in measures with which all are familiar.

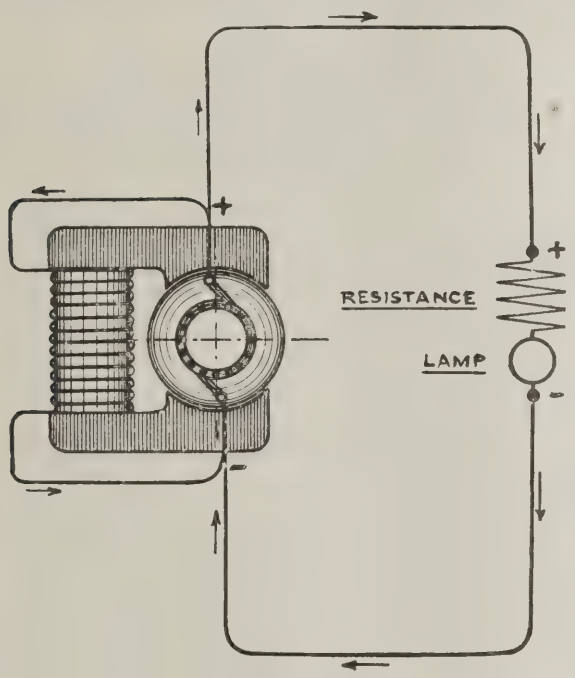

Fig. 28.

The ampère, the unit in which the quantity of electricity conveyed in a current is expressed, is that quantity flowing for one second of time through a solution of nitrate of silver in water, which deposits 1·12 mgr. of silver. It may also be measured by the power of the magnetic lines of force which it is capable of creating when conducted along a coil of wire; and on this property is based the construction of the modern ampère-meter, or ammeter.

The ohm, the unit in which resistance to the flow of a current of electricity is expressed, equivalent to friction in mechanics, is the resistance of a column of mercury having a sectional area of one square millimetre, and a length of 1063 mm., at a temperature of 0 deg. Cent. That is to say, if a current of one ampère with an electromotive force of one volt, is applied to the end of the column of mercury, the resistance is just sufficient to absorb the whole of the current by converting it into heat, so that none is available at the other end.

The volt, the unit in which the electromotive force caused by a difference of electric potential in a conductor is expressed, or, as it is sometimes called, the pressure of a current, is that electromotive force which produces a current of one ampère in a conductor whose resistance is one ohm.

The law discovered by Dr. Ohm, and called after him Ohm's law, may be expressed as follows:—

The electromotive force necessary to cause a current of electricity to flow from one point to another in a conductor measured in volts is equal to the quantity of the electricity measured in ampères multiplied by the resistance of the conductor measured in ohms. Thus 1 volt = 1 ampère × 1 ohm, or 1 ampère = 1 volt ÷ 1 ohm. To illustrate more clearly the relation that exists between these three units, we will again refer to our illustration of the bent tube filled with air—see Fig. 5.

When the tap is turned on full, so that the air can pass freely from one side of the tube to the other, if the piston is moved there is very little resistance to the movement, and very little pressure need be applied to cause it to move. If we now half close the tap so that the opening is only half as large as it was when turned on full, the resistance to the passage of the air is twice as great as it was before, consequently twice the pressure must be applied to the piston to move it the same distance in the same time.

When the tap was turned on full, if a pressure of 1 lb. applied to the handle of the piston was sufficient to move it 1ft. in one second, assuming that the area of the piston is one square inch, 12 cubic inches of air will pass through the tap in one second; and when the opening in the tap is reduced by one-half, so that twice the resistance is offered to the passage of the air, twice the pressure, or 2 lb., must be applied to the handle of the piston to send the same quantity of air, 12 cubic inches, through the tap in one second. Or if 1 lb. pressure is applied, only 6 cubic inches of air will

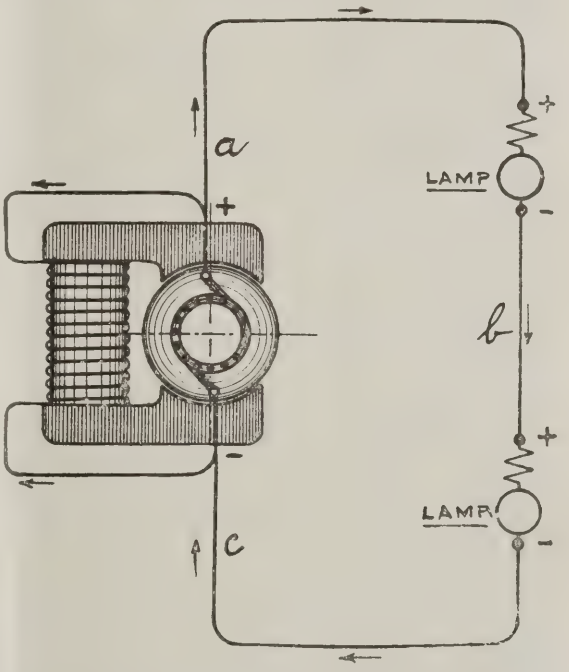

Fig. 29

pass through the tap in one second. The ampère, the ohm, and the volt bear the same relation to one another when a current of electricity flows through a conductor, that the quantity of air, the resistance offered to its passage dependent on the size of the hole in the tap, and the pressure applied to it by means of the piston bear to one another in our illustration.

Let it be assumed that in a circuit supplied with a constant current from a generator having a difference of potential of 100 volts between its positive and negative terminals, we wish to connect some arc lamps constructed to work with a difference of potential of

40 volts between each of their positive and negative terminals, the quantity of current required by each to give the requisite candle-power being 10 ampères.

Now, since according to Ohm's law, ampères = volts ÷ ohms, then ohms = volts ÷ ampères, and in our example we have 40 volts and 10 ampères, so that the resistance of each lamp will be 40 ÷ 10 = 4 ohms.

To connect a single 40-volt 10-ampère lamp to the 100-volt circuit, we should have to increase the resistance of the lamp to 10 ohms by adding to it an extra resistance of 6 ohms, so that 10 ohms × 10 ampères = 100 volts, thus involving a loss of 60 per cent. of the electrical energy—see Fig. 28. We can, however, double the efficiency of the installation by connecting two lamps in series, that is, one behind the other, so that the same current flows through each lamp in succession, but the arrangement necessitates always having both lamps alight simultaneously. In this way the resistance of the lamps is increased to 8 ohms, and it will be necessary to add an extra resistance of only 1 ohm to each lamp to give the requisite voltage. Fig. 29 shows the arrangement.

It may be mentioned here that it is always advisable or even necessary to add some extra resistance to each arc lamp, as this is of assistance to the mechanism for feeding the carbons in producing a steady light.

Since the difference of potential between *a* and *c* in Fig. 29 is 100 volts, and the resistance 10 ohms, a current of 10 ampères will flow from *a* to *c*, and the resistance between *a* and *b* being only 5 ohms, the difference of potential between *a* and *b* is 50 volts, and between *b* and *c* also 50 volts, making a total of 100 volts between *a* and *c* with a constant current of 10 ampères flowing from *a* to *c*.

As a current of 10 ampères is required for each lamp at a pressure of only 40 volts, the resistance of each lamp being 4 ohms, the extra resistance of 1 ohm is required only to reduce the voltage by absorbing a portion of the current.

The conducting wire may be compared to a tube of uniform bore throughout, but with a diaphragm in the centre having a piston on one side of it and an outlet hole on the other side—Fig. 30. If the air on one side of the tube is compressed by means of the piston, the pressure on the piston side of the diaphragm will be greater than the pressure on the other side, and the difference of pressure will depend on the size of the opening in the diaphragm and on the outlet hole; for if the diaphragm is entirely closed there will be a certain pressure on the side where the piston is, but on the other side there will be none, and if the diaphragm is entirely removed the pressure will be uniform throughout the tube, and any intermediate difference of pressure will depend on the size of the opening in the diaphragm. The piston in this case may be compared with the generator, the outlet hole with the resistance due to the arc lamp and the diaphragm with the intermediate resistance to regulate the pressure of the current flowing through the lamp.

Again referring to our illustration of the bent tube, this time having two taps instead of one, as shown in Fig. 31, a movement of the piston in the direction indicated by the arrow compresses the air at *a* and produces a partial vacuum at *c*, and if the air is compressed to 1 lb. per square inch at *a* the vacuum at *c* will have a pressure of 1 lb. per square inch also, but negative to the pressure at *a*, so that the difference of pressure between *a* and *c* will be 2 lb. per square inch.

Assuming that both the taps are closed, the condition of the air at *b* is the same as that of the air outside surrounding the tube, and in respect to the air inside the tube at *a* and *c* neutral. The difference of pressure between *a* and *b* will therefore be 1 lb., and between *b* and *c* 1 lb. also, making a total of 2 lb. between *a* and *c*. If the openings in both taps are alike they both offer the same amount of resistance to the passage of the air, and if they are both opened simultaneously the air will rush from *a* into *b* and from *b* into *c* with a uniform velocity without affecting the condition of the air at *b*, which still remains neutral, assuming, of course, that the initial pressure on the piston is kept up. This is obvious, for if the air at *b* were compressed to the same degree as at *a* no air would pass from *a* to *b*, and likewise if rarified to the same degree as at *c* no air would pass from *b* to *c*.

This serves to illustrate the condition of the electric current at different points in a circuit when lamps or motors are connected in series—see Fig. 29—and also the nature of the current at the positive and negative terminals of a generator; the one being comparable to the outward pressure when air is compressed in a tube, and the other to the inward pressure when a vacuum is formed in a tube.

The power of a current of electricity is the product of the current as measured in ampères, and the difference

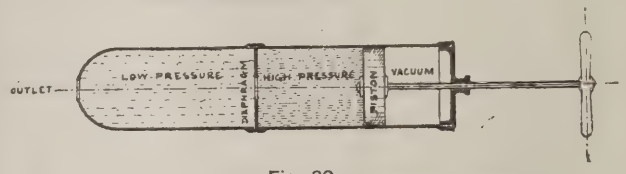

Fig. 30

of potential or pressure as measured in volts between any two points in a circuit intercepted by a resistance, which may be a motor or a lamp, or even a more or less imperfect conductor; and at any given instant this power is theoretically equal to the power which a motor or any other resistance exerts at the same instant in doing a certain amount of work.

For instance, an electric generator connected with a circuit for supplying a motor with current supplies only just sufficient for the work which the motor has to do, and when the load is taken off the motor the current is only sufficient to overcome the resistance to the flow of the current in the conductors and the resistance to the rotation of the armature caused by the air and by the friction in the bearings of the armature spindle; and just as in our illustration we showed that the pressure of the air on one side of the tap is a positive pressure when the piston is moved, and on the other side a negative pressure, so the pressure or potential of the current in the circuit is positive on one side of the

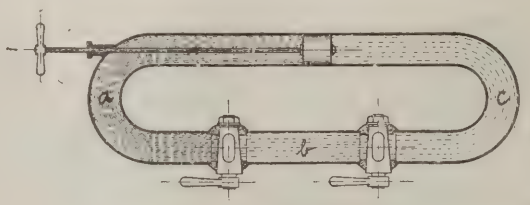

Fig. 31

motor or other resistance, and on the other side negative. The difference between the pressure of the air on each side of the tap is that available for work and represents the potential of the current.

As there is no loss of air in the air pump when the air passes from one side of the tap to the other, but only a transmission of power by the aid of the air molecules, so there is no loss of current when this is used for driving a motor or for producing a light, but only a reduction of potential in doing work.

The action is merely a change of condition instantly transmitted along a metal conductor. The current carries the initial motive power, comparable to air under pressure, to the point at which the work has to be done, which may be the vibration of carbon molecules to produce a light, or the creation of magnetic lines of

force to drive a machine, or the production of heat in overcoming the resistance of an imperfect conductor; and for comparison it may be said that, like the air molecules in our air pump, after doing its work, it passes on at a lower pressure to the minus or negative wire there to equalise the potential. As a continuous working pump would gather up the air molecules and again compress them, so the dynamo continually creates a condition of difference of potential, and thus supplies a constant current of that force which we term electricity.

THE STAINES RESERVOIRS.*

By M. Mawson, A.M.I.C.E.

In the month of November, 1900, according to the latest published return, 57 per cent. of the water consumed in the metropolis was procured from the river Thames, about 21½ per cent. from the river Lea, and the remainder, 21½ per cent. from springs and wells in the Thames and Lea valleys. A very small quantity, used only for sanitary purposes, is obtained from certain ponds at Hampstead and Highgate, but this amount is practically negligible.

The average daily flow of the river Thames during the years 1883-1899, according to the gaugings taken by the Thames Conservancy at Teddington Weir, amounted to 1131 million gallons in twenty-four hours. As the intakes of the water companies are situated above Teddington, it is necessary, in order to arrive at the flow of the river which can be compared with the rainfall on the watershed, to add the quantity abstracted by the companies. This quantity, which is a constantly-increasing one, was, during the same period, 97 million gallons a day on an average. Adding to this the quantity gauged at Teddington, we have 1228 million gallons daily available on the average of years for the supply of the metropolis, after the requirements of the river have been met.

What constitutes the legitimate requirement of the river has been the subject of much discussion in times past. As many different figures have been put forward as there are interests concerned; but the Thames Conservancy—a representative body having charge of the river—has agreed, before two Royal Commissions, that all requirements can be met if a quantity of water not less than 200 million gallons daily is at all times allowed to flow over Teddington Weir.

Some witnesses before the Royal Commission on Metropolitan Water Supply, in 1898, desired to place the limit at 100 millions a day, if a half-tide weir were erected at Wandsworth similar to that existing at Richmond, with the object of ensuring that no undue extent of foreshore shall be uncovered at any state of the tide. Above Teddington the man visiting the river for pleasure knows not whether 100 or 200 million gallons are passing down, nor does he greatly care, so long as the water is held up at the proper level in the several reaches; and it must be remembered that there are always a sufficient number of freshets to keep the river in good condition.

The problem which has to be faced by the companies drawing their supplies from the river is then, to provide such an amount of reservoir capacity that even in dry years like 1893, 1898, and 1899 they may be enabled to supply the whole of the water which their districts may demand without reducing the flow at Teddington below the limit laid down.

The Royal Commission presided over by Lord Balfour of Burleigh in 1893 considered this question in great detail, and examined several schemes put forward for the construction of the necessary storage in different parts of the Thames Valley. Most of these schemes were based on the assumption that natural valleys would be utilised in the manner usual in hilly districts, the difficulty in the present case being, generally speaking, to find a valley with a sufficiently narrow entrance and a water-tight bottom of an area great enough to hold the required quantity with economy. The system adopted must also be capable of any extension as the demand for water increases.

The proposal favoured by the Commissioners was that placed before them by Mr. Walter Hunter, M.I.C.E., and the late Mr. Alex. Fraser, M.I.C.E., the former a director of, and the latter at that time engineer to, the Grand Junction Water Company. By this scheme the flat country in the lower part of the Thames Valley between Windsor and London was to be utilised for the construction of artificial reservoirs, formed by the erection of banks containing a core of puddle carried down through the stratum of gravel which covers the whole area, and tied into the sheet of London clay underlying the gravel. The question of the most economical height of bank and depth of excavation must be determined by the location and required capacity of each instalment of the work, as also whether the water should be put into the reservoir and let out wholly or partially by gravitation or pumping, it being obviously desirable, if expense permit, to fill the reservoir quickly by gravitation when the river is high and to empty it by pumping only as and when the stored water is needed for purposes of supply. Unfortunately there are not many sites where the level will permit of this desirable state of affairs without the use of a long conduit for the conveyance of the water from some point higher up the river.

In the year 1895 the Grand Junction, New River, and West Middlesex water companies, being in want of a further supply, instructed Mr. Hunter, in association with Mr. R. E. Middleton, M.I.C.E., to carry out an instalment of this scheme, providing enough reservoir capacity to enable them to afford an aggregate additional supply to their consumers of 35 million gallons daily, under the statutory condition that none of this water should be taken from the river in such a way and at such a time as would reduce the flow at the point of intake below a quantity which corresponds to the flow of 200 million gallons daily over Teddington Weir. This quantity is fixed by the Staines Reservoirs Act of 1896 as being 300 million gallons measured at Penton Hook below Staines, where the Thames Conservancy are constructing a new weir specially adapted for measuring purposes.

The apparent discrepancy between the figures at Penton Hook and Teddington is due to the fact that the existing companies drawing their water at Hampton have already powers to draw certain quantities at that point, and the 200 limit at Teddington is, it must be remembered, the "actual" and not the "natural" flow. The quantity which may be supplied to the consumers direct from the river may be increased by consent of the Local Government Board, from 35 to 45 million gallons a day, to meet possible cases of emergency. The total quantity of water which the Staines Reservoirs Joint Committee is permitted to draw daily is 100 million gallons, of this 35 millions will pass, if required, directly to Hampton down a conduit to be hereafter described, leaving 65 millions as the quantity which can be pumped into the storage reservoirs, to be be held for use when no water, or only a portion of the 35 million gallons required daily, can be drawn at the intake without infringing upon the condition imposed at Penton Hook Weir.

It is to be distinctly understood that there is no obligation on the part of the Joint Committee to make up the flow at Penton Hook to the specified minimum of 300 millions should the natural flow of the river not come up to that standard. It is merely stipulated that

* Paper read before the Civil and Mechanical Engineers' Society, on Thursday, February 7th, 1901.

no action on their part shall reduce the flow below the minimum. It is only in exceptionally dry seasons that this state of things will obtain, and then only for a few days. In some years there will be practically no draught upon the reservoirs, while in a summer such as that of 1899 they would be used to their utmost.

The point of intake, at which the whole of the water will be drawn from the river, is a few yards above Bell Weir, about a mile above Staines Bridge. The entrance to the conduit is protected, first by a row of fender piles carrying a floating boom to prevent the approach of boats or floating timber. Inside this is a semicircular screen of wrought bars spaced ¾in. apart. Inside this grating, and separated from it by the width of a gangway, is a row of copper wire gauze screens of the usual description, arranged in double grooves so that a duplicate can be dropped in before any particular screen is lifted out for washing, an operation which will be performed on a paved platform on the down-stream side of the intake, the screen being conveyed thither on a trolley running on the gangway above mentioned.

Having been freed from floating impurities, the water will pass through four sluice openings, each 5ft. 3in. wide and with sills 6ft. 4in. below the "ordinary summer level" of that reach of the river, at which level as nearly as possible the lock-keeper is supposed to maintain it. Each sluice opening is closed by a cast iron penstock with gun-metal faces, actuated by a direct-acting hydraulic cylinder in the sluice house above. At either end of each opening is another chamber into which a penstock similar to the working door, but with a hardened face, may be lowered for the purpose of repairing the main door when the chamber has been emptied. The house over the sluice chambers is somewhat ornamental in character, in view of the commanding position which it occupies on the bank of the river. At one end is a tower, containing the accumulator for the hydraulic machinery, and tanks for the supply of water to this machinery and for general purposes.

The machinery consists of a gas engine, a set of three-throw hydraulic pumps, the accumulator above mentioned, and the sluice cylinders, four in number. A hand-pressure pump is also fitted in case of a breakdown. The accumulator is loaded to 700 lb. per sq. in.

Water for washing the screens and general purposes will be provided by a small centrifugal pump, so arranged that it can draw from any sluice chamber, and deliver direct to a hose connection on the washing platform, into the storage tank in the tower, or into the fire service. An oil gas plant is provided in a separate building capable of supplying sufficient gas for several days' use for engine and lighting purposes. Adjoining the sluice house, a pair of cottages is provided for the accommodation of workmen, each having a sitting-room, kitchen, three bedrooms, bath-room, and offices. The elevation is designed to harmonise with the sluice and gas producer houses. A small wharf is available for landing material from the river if desired.

Having passed the sluices, the water enters the conduit proper, a concrete structure consisting of two side walls with a batter of 1 in 5 on the water face and 1 in 12 at the back, 1ft. 4in. wide at the coping level, and an invert consisting of an arc of a circle with a shord of 13ft., and a versed sine of 1ft. 3in., 9in. thick at the centre. The total depth from the coping level to the invert is 8ft. and the maximum working depth of water 6ft. 4in., the total quantity which could be passed at this depth would be 147,700,000 gallons per day, thus allowing for future extension of the reservoirs. The conduit is lined with a 3 to 1 Portland cement rendering ⅜in. thick, and the fall throughout is ·01ft. per chain, or ·8ft. per mile, an extra amount of ·08ft. each being allowed at some of the syphons hereafter mentioned. The concrete of which the conduit is composed is a mixture of 1 part of Portland cement to 4 of aggregate, the latter consisting of a selection of the ballast from the excavation, washed where necessary, the quantity of sand being determined by experiment.

At every 30ft. along the conduit an expansion joint is constructed of brickwork bonded and laid in soft asphalt, in order to allow for expansion and contraction of the concrete, or slight settlement, without permitting leakage. A joint is put in on each side of the abutments of bridges or other heavy portions of the work. About 300 yards from the intake, the conduit, in order to meet the requirements of a landowner, is constructed as a double tunnel, with vertical sides, each division being 8ft. 3in. wide, with an invert having a versed sine of 9in.; the roof has a rise of 2ft. 6in., and the total height from roof to invert is 8ft. 10in., the depth of water being as before 6ft. 4in. At the ends of the tunnels grooves are formed for stop planks, these planks being arranged to completely close the opening and so prevent the passage of flood water, should the river at any time overflow its banks, and consequently fill the first portion of open conduit.

Following upon the double concrete tunnel, in fact, built into it, is a double inverted syphon, so-called, under the Colne Brook. This syphon, which is typical also of two others on the route, is formed of two tubes of ⅜in. steel plates with vertical sides and curved top and bottom, the approximate cross section being 7ft. 6in. by 5ft. 6in., the tube being curved longitudinally to a versed sine of some 17in. to ensure the requisite depth being maintained in the river above. Each tube was built up in a temporary timber cradle, and lowered into a trench previously excavated in the bed of the stream. Both tubes being thus placed in position, a shell of concrete was deposited round and between them, the whole operation being completed without the necessity of diverting the river. These steel syphons run full, under a slight head, and an extra ·08ft. of fall is allowed at each to compensate for increased friction. Close to this syphon is a 48in. pipe for the purpose of drawing water from the Colne Brook. This pipe has its entrance protected by a grating and a set of copper gauze screens similar to those at the intake.

The bridges carrying roads over the conduit are, generally speaking, of the arch type, 12in. thick at the crown, built in 5 to 1 concrete, over a half-brick lining of brindled brick, the ends of the arch being finished with two rings and a key block. The parapets are of ordinary red brick, with stone copings and dwarf railing. The abutments are formed by a thickening of the wall of the conduit. In the case of accommodation bridges, the brick lining is omitted, the arch being entirely in concrete, while in one or two cases where the levels did not permit of the use of an arch, the bridge consists of steel decking, finished at the sides with rolled joists carrying the standard brick parapets or unclimbable fencing, as the case may be.

At about one mile from the intake the conduit passes in immediate succession under the Great Western Railway, the river Wyrardisbury, and the London and South-Western Railway. The tunnels under the two railways are double, and, generally speaking, similar to that already described, except that they are built chiefly in brindled brickwork instead of concrete. Alongside, and built into the London and South-Western tunnel, is a 48in. pipe for drawing water from the river Wyrardisbury, which here runs between the two railways. This pipe is provided with copper screens in the same manner as the intake from the Colne Brook.

The river itself is crossed by a double steel syphon constructed in the same way as that already mentioned at the Colne Brook. At this point a siding is connected with the London and South-Western Railway, and carried alongside the conduit to the pumping station, crossing the river Colne on an ordinary plate girder bridge, while the conduit passes under in a steel double syphon.

TUBERCULOSIS—INFECTION, HEREDITY, PREVENTION, HYGIENIC TREATMENT.

By A. G. Young, M.D., Secretary State Board of Health, Maine, U.S.A.[1]

(*Continued from page* 114.)

The ubiquity of the bacillus.—Some persons who should know better have assumed that the danger from the germ of tuberculosis is almost everywhere present—in our streets, in our places of business. The truth is that, in the open air, the danger of infection does not exist. The tubercle bacilli are quickly destroyed by natural agencies, as we have seen. It would seem that, if any class of persons were exposed to infection from the dust of the streets of our cities, it would be the street-sweepers. Yet, the proof has been adduced that that particular class of persons, in the city of Berlin, have a greater degree of immunity than the average citizen. Years ago Cornet showed very conclusively that the bacillus of tuberculosis may, for all practical purposes, be considered absent in our streets and in all buildings not habitually occupied by consumptive patients. Even in rooms occupied by a careless consumptive patient, the patient is himself endangered more than anyone else. He surrounds himself with a halo of infectious dust which lessens his chance of recovery.

Emphasising the fact that pulmonary tuberculosis is essentially a result of exposure to infection in enclosed spaces, we advance to a consideration of some of the special conditions under which infection occurs.

House epidemics.—The observation that successive cases of consumption occur in the same family or the same home is co-extensive with the historic period. At different epochs and in different lands these observations have not received the same interpretation. While some of the fathers of medicine believed firmly in the contagion of consumption, and strict regulations were enforced in various places at later dates, the medical profession of more modern times, until within the last decade or two, has generally acquiesced in the impression that hereditary influence explains the matter. While the doctrine of the infectiousness of tuberculosis is not the daughter of bacteriology, as has been remarked, the exact methods of modern research have confirmed the conclusions of the earlier "contagionists," and have pushed forward the doctrine of infection as the more rational explanation of such house epidemics of tuberculosis as the following:—

In a paper on "Tubercular Infective Areas," Dr. Arthur Ransome,[14] of England, gives, among others, these three illustrative cases:

I. McI., aged twenty-one, student, son of healthy parents, both living, no family history of phthisis; took ill with a cough while studying in Glasgow in 1870, neglected it, came home at the end of the session, cough got worse, found both lungs tuberculous, died of phthisis in nine months. Had one sister, nineteen, and one brother, seventeen. The former a perfectly healthy girl, nursed her brother closely; ill shortly after his death, and was dead in five months after him of phthisis. The brother, who slept with I. McI. during part of his illness, and wore his clothes after his death, showed symptoms of failing health before the sister died, and in about eighteen months died of phthisis.

A young man of the Indian navy came home suffering from phthisis. In a few months two of his sisters were taken with the same complaint, and died. A third sister married, and soon afterwards died of the same complaint; the young man also died. Later on the father was similarly affected, and died. After his death the widow became phthisical, and died also. Four years covered the whole outbreak, that is, from the arrival of this young man from India. The father was originally a very strong, healthy man, and all the children healthy up to about twenty or twenty-one, or even later. One sister still lives, and is now between forty and fifty.

In 1880 the Sisters' Convent in the village of Ferdinand, was entirely free from consumption; it is well ventilated, is high and dry, and is well drained. In the autumn of 1880, a girl of 18 was found to be consumptive. She continued to sleep in the general dormitory. One sister after another now commenced with similar symptoms, and in four months after the first case began there were nine cases in sisters who had been thought to be exceptionally healthy. Four sisters died in the course of a year. After complete isolation of the sick, the epidemic was stopped.

Dr. E. O. Otis,[15] of Boston, refers to the following case narrated by Dr. Marsh, which illustrates very well the influence of massive doses of the infection in causing pulmonary consumption to assume a specially rapid and malignant form:

A German, aged sixty-two years, weighing 200 pounds, of good family and personal history, came to him in a state of advanced consumption. Two years before he had lost a son, aged twenty-three years, from the same disease. Three months later his wife, who had nursed the son, began to sicken. She was a German, aged fifty-nine years, strong, robust, and well preserved, weighing more than 220 pounds, with a good family history. She died within twenty months, having had frequent hæmorrhages from the lungs and intestines and almost constant diarrhœa. Within five months the husband was in the condition just described; while a daughter, aged twenty-two years, worn out from constant attention to the sick, was in a fair way to become phthisical, if not already so. It was learned that all three had expectorated on the walls, floors, and in the corners of the apartment, the man preferring to expectorate under his bed. The daughter slept in the same room with the sick man, and slept beside her mother during her illness.

Dr. Otis also refers to the late history of the Apache Indians as an example of domiciliary infection.

In a community of 400 of them taken from a free nomadic life in Arizona and New Mexico and transferred to Alabama, where for four years they occupied log cabins badly constructed and situated in a low, damp hollow, and in which filth gradually accumulated "until they became veritable incubators of disease," the deaths from tuberculosis in five years were seventy-eight, or 43⅓ per cent. of the total number of deaths.

Jaccoud,[16] of Paris, among other evidences of the infectiousness of consumption presents the following case:—

In the autumn of 1872 an artisan, his wife and five children (four sons between the ages of three and a-half and fourteen, and a daughter fifteen years old) went to live in a village of Denmark, where they inhabited a small room already occupied by another family, consisting of a man, his wife, and a grown-up son affected by febrile phthisis. They remained in this crowded and confined abode, in which the air was rendered truly poisonous by the presence of the patient, until January 3rd 1873, when they left the place for a more healthy dwelling. Before this, however, at the time of Christmas, the five children, who had been previously in good health, and unaffected by scrofula, suffered from pulmonary disease, and the evolution of the complaint was so rapid that they all died after the respective

[15] "The Causes and Conditions of Pulmonary Tuberculosis, and How to Avoid them," page 6. 1898.

[16] "Curability and Treatment of Pulmonary Phthisis," page 76. 1885.

periods of seven weeks, three months, three months and a-half, and seven months. The daughter, whose age was fifteen years, and who had only remained during one day in the infected room, was attacked like her brothers, and it was her death which occurred at the end of three months and a-half.

In a lately published work by Prof. Cornet,[17] of Berlin, he presents indubitable proof of the infectivity of pulmonary consumption, particularly among the occupants of infected rooms. In connection with about 800 cases of consumption, he has carefully traced out all the available facts which have a bearing upon the questions of infectivity, heredity, or predisposition, not limiting his inquiry to the patient and his nearest relatives, but extending it to all of his available connections, fellow-workmen and associates, sometimes making a physical examination of as many as thirty persons in getting at the history of a single case. Notwithstanding the well-known difficulty in fixing the exact sources of infection which occurred months or years previously, he was able to trace out its source in more than half of his cases.

Cornet says that when a large number of apparently hereditary cases of tuberculosis are examined it must occur to the unprejudiced mind that the parents of many of the patients did not show the first symptoms of tuberculosis until after the birth of the child in question and sometimes not for many years after, or that the death of the parent from tuberculosis occurred remarkably near the time of the death of the child.

In many cases it will be found that the single cases of tuberculosis are separated by almost a generation, but careful investigation shows that in the majority of these cases a brother or sister, or other near relative who stood in intimate relation with the family, served as a connecting link between the disease of the parents and that of the child. The following case illustrates this:—

Case 136. Admitted, 1892. Auguste Vil., 31 years, married. Her father died in 1887 at the age of 64 of senile debility and asthma (?). The father's parents were very aged; her mother's parents died young. The collateral line of relatives of the father were all well, but on the mother's side all had died of tuberculosis. The mother died of tuberculosis in 1877, at the age of 47 years.

One year after the death of the mother a 16-year-old brother who had been constantly in the house, died of tuberculosis; a sister 25 years old who had been married three years, but who was infected before leaving her mother's home, died in 1897. In 1883 an 18-year-old brother died, and in 1886 another brother, 24 years of age, who slept with the other brother, died of consumption. In 1887 a brother 35 years of age died after coughing and expectorating 14 years.

The patient, Auguste Vil., showed symptoms of the disease in 1889. These children had been much together. The elder sister, 39 years of age, long absent from the paternal home, nursed Auguste Vil. for eight months, and after that coughed and raised, and shows by physical investigation, signs of consumption.

From the point of view of heredity it is hard to reconcile the fact that only a part of the children of tuberculous parents are affected, but from the point of view of infection, the fact will often be developed from a careful investigation of the family history, that some of these children were at home more than others, either on account of their tender age, incapacity for working, or from other causes, and that those members of the family who remained well were away from their home most of the time. The following case illustrates this:—

Case 8. Admitted, 1892. Auguste C., single, 24 years of age. The mother died of hæmorrhage from the lungs in 1885. The mother's father died at the age of 84; one sister, living and well; mother's mother died of cancer. Of the brothers and sisters of the patient who lived in the same room with the mother, one only, a brother 15 years of age, remains well. On the other hand, two brothers, one of 16 and the other of 14 years of age, have lately died of consumption. The patient Auguste C., became tuberculous in 1885, and in 1889 went to live with another sister 25 years of age, who is now also tuberculous.

A married sister, 26 years of age, who was away from home at the time of the illness of her mother, is well and strong, and the same is true of her children. The same is also true of a brother 22 years of age, who at the same time was away from home. A 16-year-old sister who slept in another room remains well, and so does the father, who during the illness of the mother slept in another room, and at night was away from home at his work.

The investigations of the prevalence of tuberculosis in some of the sections of New York City show that, of the infected houses, 28·2 per cent. contained 55·8 per cent. of the cases, and these occurred in only 10·2 per cent. of all the houses in the ward.

Many of the houses have had one or more cases every year for three consecutive years, some of them having had as many as eight or eleven cases during this period. Several houses, in which one or more cases of tuberculosis have been reported in the last three years, have had deaths from the same disease in them for eight or nine years, viz., five houses, in which twenty-two cases have been reported since 1893, have had thirty-six deaths from tuberculosis from 1888 to 1893 inclusive.

As Dr. Tracy, the registrar of the city, remarks:—It would appear that there is no question as to the infectious nature of the disease. Though tuberculosis causes from 14 to 15 per cent. of the total number of deaths in the city, yet it is confined within narrow limits and to a small number of houses.[18]

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

THE VALUE OF HOSPITAL ISOLATION FOR SCARLET FEVER.

A SUBJECT of immense sanitary importance was discussed at the ordinary meeting of the Incorporated Society of Medical Officers of Health, held on Friday last at the offices, 197, High Holborn, W.C. It was nothing less than the scientific calling in question the value of hospital isolation for scarlet fever cases, and in several ways the lecturer challenged popular and accepted theories in regard to the matter. In view of the freshness and effect of the problem there was a very large attendance of members and friends. Dr. J. C. McVail, the president, occupied the chair, and those present included Mr. Wolf Defries, Drs. J. T. Wilson, W. H. Symons, C. Sanders, W. A. Bond, M. Gapp, J. H. Beale Collins, Shirley Murphy, A. Newsholme, J. C. Johnson, G. Newman, E. F. Willoughby, W. Groves, H. Kirkwood, H. R. Farrar, J. Robinson, G. E. Yarrow, J. Williamson, Childs, J. S. Tew, G. Millsom, P. Boobbyer, H. M. Richards, A. Griffiths, G. H. Day, D. A. Waite, D. L. Thomas, D. S. Skinner, J. Kelland, A. G. K. Cameron, A. C. Pearson, W. E. Godbet, and Dr. F. J. Allan and H. Kenwood, the hon. secretaries, and many others.

Dr. C. KILLICK MILLARD, M.D., D.Sc., the Medical Officer of Health of Burton-on-Trent, and late Medical Superintendent of the Birmingham City Fever Hospitals, gave the paper, the subject of which was "The Value of the Hospital Isolation of Scarlet Fever." He said

that he fully realised the great importance of the subject of the paper, which had not been written without due consideration. He had not the slightest prejudice against isolation hospitals; in fact, he had every reason to feel favourably towards them. But the paper had been written from absolute conviction, and he had been careful not to say anything more than he believed the facts he had ascertained justified. Fair criticism would be welcome, and no doubt there would be plenty of it. His observations were strictly limited to the hospital isolation of scarlet fever. There had been a tendency in the past to treat the isolation of all infectious diseases as one question, but that was a mistake. It by no means followed because isolation hospitals for small-pox, cholera, or typhus, had been of the greatest value, that they would also be of value for such a disease as scarlet fever. Having given some quotations to show the orthodox opinion with regard to isolation hospitals, he could say, on the authority of Sir George Buchanan, that isolation in hospital for scarlet fever was received as an accepted principle of public health work without being founded on any basis of statistical proof. That proof had not, since the adoption of the principle, been forthcoming, and therefore he had taken upon himself to collect statistics to show what the real position of affairs is. In response to his inquiries he had received 113 returns, 31 being from the great towns, 81 from smaller towns, and one from the county of London. He desired to express his indebtedness to the Medical Officers of Health of all these towns for the ready way in which they had helped him. It was a significant fact that fifteen out of the thirty-one Medical Officers of the great towns preferred to express no opinion on the subject, and among the small towns about the same proportion were also not prepared to commit themselves; nearly the whole of the remainder expressed themselves as in favour of hospital isolation for scarlet fever, but a few were doubtful. He attached great importance to these facts, as showing that a considerable measure of doubt existed to-day in regard to the subject. Dr. Millard then exhibited a number of carefully-prepared diagrams of the large towns, and exhaustively showed the results of analysis of the returns in such towns as Huddersfield, Nottingham, Bradford, Preston, Swansea, Warrington, the object being to discover how far hospital isolation had affected the prevalence of scarlet fever. The practice, however, it was shown by the mass of figures presented, had little if any effect in reducing the prevalence of the disease, even in towns where as high a percentage as 90 of those attacked were removed to hospital. The same result was obtained if groups of towns were taken instead of individual towns, while in addition it could be seen in some cases where hospital isolation was not provided to the same extent as in others, the position of those towns in regard to scarlet fever was even better. In certain places, too, it could be seen that scarlet fever was more prevalent after isolation had been practised than before; but on the whole the many isolation hospitals all over the country had not that result in diminishing the disease that would naturally have been expected after a considerable period of trial, and this, too, with the increase of preventive measures outside the hospitals as the standard of sanitation was gradually raised, and also in spite of the increase of public education as hospitals and sanitation increased. He had, after prolonged and minute inquiry, as indicated by the diagrams and tables displayed that evening, come to the conclusion that the isolation of scarlet fever patients had failed to materially reduce the prevalence of the disease, and that it had failed also to reduce its fatality, while in some towns there was some reason to fear the fatality of the disease had even been increased. His object in reading the paper was to draw attention to the facts, whatever construction might be placed upon them, and how important it was to arrive at some sound and safe conclusion could be imagined from the many expensive schemes for isolation hospitals which were being carried out in many parts of the country. The argument that the system had not been given a sufficiently thorough trial, would not hold good, when it could be seen that towns which isolated most thoroughly were now no better off as regards the disease than those towns which isolated less. One explanation given was that the spread of the disease was due to unrecognised cases; no doubt such cases did play an important part in the dissemination of disease, and it would be a good explanation why the disease was not entirely stamped out, but these unrecognised cases would not explain why this disease remained as prevalent as ever in spite of from 80 to 90 per cent. of all recognised cases being isolated. They were forced to turn to hospital isolation to see if there were any flaw in the system itself. The theory of isolation in hospitals appeared to be sound, but it would be admitted that isolation in a hospital was not by any means the same thing as isolation at home. It was, as Dr. Marriott had recently pointed out, aggregation rather than isolation; and this aggregation had often reached a high point. Was it not conceivable that this aggregation had been productive in ways hitherto hardly suspected of evils which have to a large extent, if not entirely, neutralised the good which otherwise would have resulted from isolation? Speaking from his own hospital experience, he could say there was nothing very improbable in that; indeed, at the moment it was the explanation which seemed to him to have most claim for consideration. In the occurrence of "return cases" they had positive evidence that infection was sometimes carried from the hospital and spread outside, and these "return cases" did not represent the full extent of the evil, because such cases were defined to include only those cases occurring in a household to which a discharged patient returned. Doubtless infection which appeared to be contracted in the ordinary manner was at times due to infection from hospital. It was generally admitted that the fatality of "return cases" is higher than primary cases; if so it was a significant fact, and showed that infection carried from a hospital is more virulent. Was it possible that by aggregation a scarlet fever of higher fatality and more persistent infectivity had been produced—that they had obtained a "hospitalised strain" in our scarlet fever? Such a condition would account for the continued prevalence of the disease in spite of all efforts to reduce it. He was aware that if this theory were correct it would constitute a tremendous indictment of the whole system of hospital isolation of scarlet fever as has hitherto been carried out. That was an unpleasant thought, but in view of the facts and the *primâ facie* evidence there was a case which called for investigation. There had been no full official inquiry into the subject for twenty years, and yet fresh hospitals were still being built on the old lines as if the whole system had been a complete success, and had accomplished all it was originally expected to do (Applause.)

A long and animated discussion ensued, and Dr. Millard was warmly thanked for his paper, the preparation of which must have entailed immense thought and labour.

The Fire Brigade Committee of the London County Council proposes to adopt a sliding scale of penalties for chimney fires. For houses of which the rateable value does not exceed £20 a year, the sum, they think, should be demanded is 2s. 6d., rising to 5s. for values up to £30, 10s. up to £40, 15s. up to £50, and £1 for values beyond. Under the General Powers Act of last year the Council can recover an amount not exceeding £1 as a civil debt from the occupier.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

NEW YEAR'S PRESIDENTIAL ADDRESS.

Gentlemen,—My first duty is to wish you all a happy new year, and I trust that the present and coming years of the century we have just entered upon may be prosperous to each member individually, and also to the Institute, that not only may the number of members increase, but that there may be a continuance of the good work which has been done in the past.

I have next to most cordially thank the members of the Institute for placing me in the presidential chair, and to express my appreciation of the great honour that has been conferred upon me. I have succeeded some most able men, and I feel certain that in the future equally able men will occupy the position I now hold.

The fact that I was resident so far from the head-quarters of the Institute, and the consequent inability to attend the meetings as regularly as I should wish, made me hesitate somewhat in accepting the honour, but I felt assured that the Institute would not suffer owing to the able and enthusiastic Council by which the business of the Institute is so admirably conducted. Under its earnest and careful guidance the Institute is destined to exercise considerable influence in furthering sanitation in all its branches, more especially in the construction and arrangement of buildings, works, or appliances devoted chiefly to sanitary requirements. Since receiving the appointment of president I noticed a paragraph, in one of the weekly papers, which was devoted to discussing "What a Sanitary Engineer is," and taking exception to a Medical Officer of Health being connected with an association of (whatever they are) Sanitary Engineers.

In the first place, the term Sanitary Engineer appears to me to need little explanation. The term Military Engineer is one well known to apply to an engineer who devotes himself chiefly to the construction and superintendence of works for offence or defence. A Mining Engineer is one employed in the construction or working of mining undertakings, and a Sanitary Engineer similarly denotes one who devises plans for the construction of sanitary works or appliances or who is employed in superintending the working of the same. The arrangement and working of sewerage schemes, hospital construction, and the fixing of various sanitary arrangements are among those matters which come under the supervision of sanitary engineers. Without speaking of my own qualifications for the office of president—a matter which your Council has already taken into consideration—it must be acknowledged that the great improvements which have taken place during recent years in erections and appliances devoted more especially to the advancement of sanitation have been the result to a very large extent of the recommendations of Medical Officers of Health. Than your late president I think you could not have a better example of what a sanitary engineer is. His connection with sanitary improvements in the town with which he was so much associated was most intimate, and very many of the conditions which exist in that town to-day are due directly or indirectly to his suggestion and foresight. I feel bound to refer with regret to the loss this Institute has sustained by his death. That he was possessed of considerably more than the average share of human ability, I think the position he attained to in the architectural and antiquarian world was a proof, and the advice he was ever ready to give could always be relied upon as sound and thoroughly practical. His influence was exceedingly wide and extensive, and many districts are reaping the benefits of his advice given in a private or unofficial capacity.

For this institution he had a very warm feeling, although he only became acquainted and connected with it late in life. His chief hobby or interest was, however, the Order of St. John of Jerusalem, of which Order he held the highest position he could attain, viz., a Knight of Justice; and in the work of this Order, the St. John Ambulance Association, and the Eye Hospital at Jerusalem, claimed a considerable amount of his time and attention.

In a meeting of such an institution as this, at the commencement of a new century, one can hardly refrain from looking back to the progress made in sanitary engineering during the century that has just gone, and the great strides which have been made in our knowledge respecting sanitary matters during the years contained in it. The advance has been made chiefly in the latter years of the century, but the earlier ones were occupied in the study of matters, such as "Microscopy," which paved the way for this advance.

The knowledge of diseases carried by water, or air, and milk, and the influence of soil upon disease, are matters of which we knew nothing before the past century.

The knowledge and practice in the earlier part of the century in respect to house sanitation may be gauged by the position, construction, and arrangements of the older houses in our towns and villages, which so frequently require our attention from some insanitary condition or from their endemic relation to disease.

The disposal of sewage and the construction of works for that purpose are perhaps the latest problems in sanitary engineering, and the difficulties connected with the housing of our rapidly-increasing working class communities will afford matter for discussion and thought for some years to come.

One sanitary provision has seen during the past century many changes and a gradual improvement in its construction, viz., the ordinary closet, or apparatus for containing or collecting the excremental matter from our houses; and as a new form of closet is now coming into use in many of our larger towns, I have to-night chosen to give my experience of the working of the comparatively recently introduced waste-water closet.

Probably the earliest record of any bye-laws relating to the disposal of excremental refuse is in the Mosaic Law, where you will find enacted that each one who wishes "To doe as neede and nature hath vs taught," must go outside the camp, dig a hole with a spud (attached to his spear) and after use cover over the same with soil before going back to the camp. The nomadic conditions of the camps and the sparse resident population allowed this course to be adopted, and it cannot, under these conditions, be looked upon as anything but in accordance with sanitary principles. It is really earth treatment with the largest possible supply of earth. We find that many savage tribes have special places in which their midden heaps are situated. These heaps are used for certain periods and then covered with soil, on which rank vegetation quickly grows.

The next stage of disposal appears in conjunction with drainage construction, for we find that in many of the fashionable cities of history, notably in Rome and Athens, probably Babylon and Egypt also, very elaborate systems of drainage were constructed, and there is no doubt that a form of water-closet was in use in some of these cities. For centuries after this period, however, conservancy methods were those adopted, not only in this country but in most other civilised ones.

The earliest form of closet was a simple pit in the ground, similar to those used by ancient and uncivilised tribes, which was kept in use until full, when it was covered over and a fresh one dug. Next a cross bar was placed as a rest for the person using the receptacle, and in course of time the pit was enclosed by walls and covered by a roof, ensuring both privacy and protection from the weather.

Up to this condition the receptacle was simply a hole in the ground, partially emptied at intervals as it became full, and a greater part of the liquid contents draining away through the surrounding soil, often to a neighbouring well or watercourse. The cesspool was then lined and floored with bricks, purposely arranged to allow free drainage between them, and it is only in a comparatively recent period that water-tight receptacles have been insisted upon. As a further development of the water-tight closet, the removable pan or can made its appearance, and under these conditions we find the closet of to-day. The water-tight cesspool we find in so many continental cities. They are emptied at regular intervals by an air-tight force or suction pump, and in a less complete condition we find them in this country also. With the movable receptacle the closets of many of our large towns are generally supplied—either in the form of tubs, cans, earth-closets, or other variation of the system. Though all, I think, at the present day are willing to admit the superiority of the movable receptacle, with frequent removal, over the old cesspit—even if a water-tight one—there are a great number who will not admit that the other form of sanitary convenience, viz., the water-closet, has any advantage over the pan closet, and some who even consider that the water-closet has distinct disadvantages which the pan system has not. Though, as I have said before, the Romans and others had probably some form of water-closet, the earliest described in this country was about the year 1600, when Sir John Harrington invented one for his own use.

The general use, however, did not commence until the beginning of the century which has just passed, or a few years before it commenced. There were in the early part of the century very few houses to which they were fixed, and the reputation which they gained has not always been a satisfactory one—due to a faulty construction and bad workmanship in fixing—and it is only in the latter decades of the century that these appliances have been properly constructed and suitably fixed. I think you will all agree that the water-carriage system of removal of refuse of an excremental nature from the neighbourhood of our dwellings has, in most respects, great advantages over any of the conservancy systems.

There are few now-a-days who would not prefer, at any rate in the house in which they reside, the water-carriage system, and every investigation of which I am aware tends to prove that the water-carriage system has in connection with it a lower death-rate than the dry system. The greatest advantage is the quick removal of the waste material from the neighbourhood of dwellings, and in consequence the removal of a common source of certain infective diseases. The soil round and near the receptacle does not become contaminated, as is so frequently the case when either cans or other similar receptacles are employed.

When cans, earth-closets, &c., are properly made probably there is little soil pollution, but even when the greatest care is exercised some of the contents are spilled when the receptacles are being changed or emptied, causing surface pollution, and in all that I have yet seen there are corners and hidden angles which are exceedingly liable to become offensive, and they are not to be compared, even when most favourably constructed, with the simple condition of the best water-closets, every part of which can be reached for the purpose of cleansing. Even when the conveniences are themselves satisfactorily constructed and maintained, the retention of the putrescent material near to dwelling-houses is itself a danger to health.

(*To be continued.*)

The Haverfordwest Town Council has decided to borrow the sum of £1365 for paving works.

SEWAGE TREATMENT AT BOLTON.

The following report on the management of the Bolton sewage works has been made to the chairman and members of the Scavenging and Sewage Committee of the Bolton Town Council by the engineers, Messrs. Hinnell and Murphy. A diagram was appended, showing the amount of oxidisable matter contained in the raw sewage, tank effluent, and filtered effluent as compared with the standard adopted by the River Authorities, also the daily sewage flow and amount of sludge formed and the varying degrees of purification effected by the treatment of the sewage. The report states :—

In completing our supervision of these works at Hacken and Rhodes Farm we beg to report upon the same to the end of last year. Since our half-yearly report of July last, the quantity of sewage treated for the six months ending December 31st has been 960, 832, 844 gallons, and the quantity of liquid sludge formed and dealt with has been 24,680 tons.

We have experienced much difficulty in dealing with tank effluent at Rhode Farm in consequence of the amount of solids in solution it contained caused by the liquefaction of the sludge in the settling tanks. With the completion of the sludge-pressing installation, however, it will be possible to deal with the sludge formed weekly and enable the tank effluent to be sent down to Rhodes Farm filtration works in a much lighter condition in the future ; the works can also be much better maintained, and at considerably less cost when the additional tank accommodation as proposed is provided. During last year we are pleased to report that we were able to reduce the amount and value of chemicals used to about one-half, viz., from £1400 to £700, and the extent of purification of the sewage has been fully maintained.

During the last six months we have made 234 tests according to the general formula of the Joint Rivers Committee, and it is satisfactory to note that of this number 222 are under the standard of purification adopted by the Joint Rivers Committee, and only twelve slightly above that standard. The amount of purification effected in the organic matters contained in the sewage has averaged 88 per cent., as shown by the testing of the Rhodes Farm effluent.

The revenue obtained from the sale of produce grown upon the farm for last year will probably amount to £400, and this might have been doubled or trebled if live stock had been kept upon the farm to consume the produce which had necessarily to be cultivated to prevent the land becoming rank or sewage sick.

The filtration plots, having a deep subsoil of coarse gravel, we have utilised as bacteria beds for the night flow of tank effluent, and these, with an occasional turning over of the surface, have produced satisfactory results.

We regret that no diminution of tannery and other refuse waters has yet been made, but if anything the quantity delivered to Hacken Works has increased, and we must again express our conviction that the continued success of the works is jeopardised by its admission into the sewage flow.

In concluding this report we wish to acknowledge the great attention and consideration you have afforded in enabling us to so far complete your sewage purification works as to effect the purpose for which they were designed at a minimum of cost and attention.

The capital expenditure upon sewerage and sewage works for the borough of Bolton in proportion to the population is still considerably less than other Lancashire towns, and the efficiency of your sewage purification works is still far superior to the results obtained

from sewage works of other large towns. We feel sure that it must be gratifying to you to know after acquiring Rhodes Farm that recently Leeds has determined to spend £700,000 upon a conduit and land filtration works after experimenting for three years with bacteria beds. Birmingham are now increasing their present sewage farm by 400 acres, and Nottingham are spending about £335,000 in extending their sewage farm, as successful purification with land treatment at these places has become assured owing to careful and judicious management.

CORRESPONDENCE.

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

IS AN ENGINEER AND SURVEYOR A CIVIL ENGINEER?

SIR,—I am very interested in reading your admirable comments on the propriety of an engineer and surveyor being entitled to be called a civil engineer. If he is so entitled, it follows, as a matter of course, that he is free to use the recognised abbreviated form, initial letters C.E. I believe, however, you have centred the question when you say, "the matter is one which must be decided by a man's conscience and taste." A reference to extracts from the Charter of the Institute of Civil Engineers may here prove useful. It "was first established, and has since been incorporated by Royal Charter, for the general advancement of mechanical science, and more particularly for promoting the acquisition of that species of knowledge which constitutes the profession of a civil engineer; being the art of directing the great sources of power in Nature for the use and convenience of man, as the means of production, and of traffic in States both for external and internal trade, as applied in the construction of roads, bridges, aqueducts, canals, river navigation, and docks, for internal intercourse and exchange; and in the construction of ports, harbours, moats, breakwaters, and lighthouses, and in the art of navigation by artificial power, for the purposes of commerce; and in the construction and adaptation of machinery; and in the drainage of cities and towns." I think we should all accept the above definition in its entirety, and specific branches of engineering which have been developed during the past eighty years, since the first president, Thomas Telford, F.R.S., occupied the chair in 1820, appear to be provided for by the somewhat comprehensive enunciations in the first part of the Charter. It may be observed that an engineer being a surveyor does not help his case much, as regards bringing him under the above denomination. But if a man has a knowledge of and follows any of the above branches of engineering as a profession—if he is not a civil engineer, what is he?

I am unable to traverse the assertion that an objection to engineers who are not members of the Institute of Civil Engineers using C.E. may have been made, but I doubt if it is a representative view of the whole body, and I know of few institutions whose members comprise men more gentlemanly in feeling and education than those of the Inst. C.E., which is by its Charter a scientific institution and not a trade union. A civil engineer who is not a member of the Inst. C.E. should, I think, be extremely careful not to lay himself open to any suggestion of sailing under false colours; he should bear in mind that his lay brethren may be unaware of any difference between the abbreviations C.E. and M. Inst. C.E. or Assoc. M. Inst. C.E., &c. The user of C.E. should also recollect that his employers may construe C.E. as signifying a profound and universal knowledge of all branches of the profession, or that the user has at one period of his life history been engaged upon bridge building or railway work.—Yours faithfully,

AN ENGINEER.

February 8th, 1901.

STREET CLEANING AND SCAVENGERS.

SIR,—Questions of practical importance are coming before the new Borough Councils in London, and if they are able to bring about an improvement in such matters as the cleansing of the streets they will secure wide and lasting popularity. London is much nearer the sea than Paris, and the Thames is far wider than the Seine, yet the French capital somehow enjoys an ample water supply to wash the streets clean, while in London our thoroughfares are sprinkled just sufficiently to churn up a greasy mud. In Berlin, again, the cleaning of the streets is carried out in a systematic and efficient manner. The street sweepers work in relays—a day and night shift—of twelve hours each, with intervals for meals. Mr. James Pollard, C.A., chairman of the Edinburgh Public Health Committee, and secretary of the Edinburgh Chamber of Commerce, in a work published a few years ago on the municipal government of Berlin, dealing with the cleaning of the streets, writes:

"In connection with this part of municipal work, there is a simple and yet very suggestive matter which strikes the visitor to Berlin who is comparing notes with the state of things at home. It is that the scavengers are all clad in overalls and wide leggings of coarse hempen stuff, which gives them an appearance of tidiness and preserves their ordinary clothes from pollution. With an official cap on his head, a belt round his waist, giving his plain, large tunic a somewhat smart appearance, the Berlin scavenger feels that he is a public servant, and that though his occupation may be menial, yet his health and comfort are of some concern to his masters. The municipality takes no credit for philanthropy in providing these overalls. On economical grounds, which are the only grounds on which any expenditure of this sort is justified, the Corporation do what they can to make their own servants an example to the community in respect of clean habits. Could anything be more consonant with common sense? There can be no doubt that our street sweepers and dustmen daily carry to their homes quantities of dirt and filth which are caught by their clothes in the performance of their unpleasant work. These clothes they wear day in and day out, often for weeks, without being washed. The dirt that is carried home is itself a source of mischief. Dirt makes dirt; and nowhere is it more likely to do so than in such homes as those of our poorer labourers. The Berlin scavenger divests himself of his canvas overalls whenever he reaches home—he may, for the matter of that, leave them behind the door—his ordinary clothes are not soiled and smeared with the dirt of his labour. He washes his hands, face and neck, and is at once in a condition to enjoy his fireside, or to take his wife and children out."

The wages of these men average twenty-one marks per week.—Yours faithfully,

J. LANDFEAR-LUCAS.

Hotel Bristol, Beaulieu, France,
February 4th.

THERE have been altogether ten cases of suspected plague at Capetown. Only one patient is white. The mortality among the rats at the docks began two months ago, and the epidemic spread to the mice in the city. Both rats and mice are now being rapidly exterminated. It was the mortality among these rodents which first aroused suspicion, and led to the detection of the plague.

REPORT ON AN OUTBREAK OF ARSENICAL POISONING IN CREWE IN 1900.

By Dr. Alfred Greenwood, M.O.H. Crewe.

In common with the Medical Authorities of Manchester and Salford, several medical men in Crewe had been puzzled since last August by the presence, in many of their patients, of symptoms of peripheral neuritis, together with other indefinite, vague symptoms which were not wholly attributable to alcohol, but which suggested the action of some other toxic agent.

Owing to the discovery of Dr. Reynolds, of Manchester, that a possible cause for these indefinite symptoms might be in the contamination of beer by arsenic, and the subsequent verification of the same, additional light was thrown on the subject. It was, therefore, with the object of showing to what extent the outbreak of arsenical poisoning affected Crewe that I wrote this article, in my capacity as Medical Officer of Health for that borough.

My first act was, on November 30th, 1900, to send a circular letter to the medical men in the town, asking them if they would kindly bring to my notice any cases which they suspected to be due to arsenical poisoning from beer. In answer to this I received information regarding thirty cases, many of whom I saw.

These cases showed some or all of the following symptoms :—Nausea, sickness, silvery tongue, and irritation of the eyes, followed by a feeling of pins and needles in the tips of the fingers and toes ; the calves were painful on pressure, and afterwards the hands became numb and useless. In most of the cases wasting of the small muscles of the hands took place. Several cases contracted dropped wrist, and an unsteady gait. A marked sign in nearly all the cases was a brownish pigmentation of the skin, very similar to that seen in Addison's disease.

Most of these cases were mild, but in two cases the symptoms were extremely severe. No deaths occurred amongst the Crewe cases, and the symptoms lasted from two or three weeks to as many months in the various cases.

It was found that all the thirty cases were beer-drinkers, and according to the histories—which in alcoholics are generally fallacious—the amounts consumed daily varied from three to ten or twelve glasses. In certain cases, however, there seemed no reason to doubt a history of three glasses of beer per diem, and hence the assumption that as far as this epidemic was concerned the amount of beer necessary to produce such symptoms as tingling in the hands and feet, &c., was much less than that required to produce the same symptoms in ordinary alcoholic peripheral neuritis.

Special inquiries were also made as to the public-houses which were most frequented by these people, and samples of beer, representing the brewers who send beer into Crewe, were taken. These were tested for the presence of arsenic by Reinsch's test. In all I examined twenty-one samples of beer and found arsenic in ten of them, which represented four brewers. Several of the public-houses containing affected beer corresponded with those which were frequented by the sufferers.

A circular letter was sent to all the brewers sending beer into the borough asking them to recall any beer about which there was the least suspicion, and also impressing upon them the necessity of taking every precaution to prevent any beer being sent out which contained injurious material. Every brewer replied and expressed willingness to take all steps which would prevent any further mischief.

A large quantity of beer was recalled, and since December no further cases have come to my knowledge.

Samples of sweets, jam, syrup, &c., were examined and found to be free from arsenic.

The following is a description of the method of performing Reinsch's test:—10 c.c. of pure hydrochloric acid were placed in a flask with 50 c.c. of water, thus making a proportion of 1 in 6. In this were placed four or five thin strips of copper foil, and the whole was boiled for about a quarter of an hour. If the foil is free from film one may assume purity of the reagents for this test. Pour away this fluid and add 200 c.c. of the sample of beer and 33 c.c. of hydrochloric acid, again making a proportion of about 1 in 6. Boil gently for half an hour; pour away the beer and wash the foil with distilled water. Transfer the foil to blotting paper, dry, and heat two pieces in a flat redaction tube and heat. The copper foil will probably be covered with a dark metallic film if arsenic is present, and these form on the side of the tube a little above the foil, which on microscopical examination are seen to consist of octahedral and square crystals of arsenious acid.

Four samples were examined quantitatively, and a description of the method employed appeared in the *Chemical News* of February 8th by Ryder and myself. This method is a combination of the qualitative test above described, together with the method used for the determination of small quantities of arsenic in iron and steel.

The estimated quantities of arsenic in the samples were ·16 grain, ·004 grain, ·01 grain, and ·015 grain arsenious acid per gallon of beer respectively.

I do not propose to discuss the source of the arsenic beyond stating that in the first instance contaminated sulphuric acid had been prepared from arsenical iron pyrites, that this sulphuric acid was employed in making glucose and invert sugar, and that these saccharine substances were used as malt substitutes in the brewing of beer. Nor will I discuss the liabilities of the manufacturers of acid, glucose, and beer, or analysts or retailers, which involve numerous points of law.

On examining the death returns for Crewe during 1899 and 1900 I do not find that there has been any increase in the numbers of deaths from alcoholism, peripheral neuritis, hepatic cirrhosis, and other diseases of the liver and stomach.

Hence the following were the conclusions which were drawn from the above investigations :—

I.—The Crewe epidemic was part of the Manchester and Salford epidemics, since the cases occurred about the same time, and the affected brewers had been receiving their glucose from the same firm which supplied the affected brewers in these two Lancashire towns.

II.—The epidemic was seen amongst beer drinkers only, and beer was the only article found to be contaminated, no arsenic being found in samples of jam, sweets, and syrup which were examined.

III.—Although two cases exhibited very severe symptoms, the mortality of the Crewe epidemic was *nil*.

IV.—The amount of beer consumed in many cases was small, not more than three glasses a day.

V.—The removal of the cause was followed by a cessation of the occurrence of cases, showing symptoms of arsenical poisoning.

An interesting report was made by the Surveyor to the Dover Council last week respecting the provision of destructor cells in connection with the new boilers at the drainage works. The total cost would be £1250. He anticipated it would save £200 worth of fuel a year; also £75 the cost of towing 1000 tons of refuse to sea. The expenses would be £55 wages and £84 interest on loan, so that the net saving would be £136 yearly. The matter was discussed, and then adjourned for a week for details to be further considered.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

HOUSING REFORMS IN MANCHESTER.

FROM reports which reach us from the big provincial centres, it is quite evident that the provinces are no less keenly alive to the importance of housing reform than the metropolis. Manchester is naturally well to the fore, and at an influential conference held last week under the auspices of the National Housing Reform Council and other bodies, although there was some diversity of opinion as to the remedy, there was perfect unanimity to the urgency of the subject. The meeting was one with the chairman, who described the housing problem as a burning question, and one that could not long be delayed. Nor were there any dissentient voices raised to combat his assertion that one of the worst features of the question was that a great deal of slum property in our cities was owned by men who were sent to the Corporation to represent the public; while one of the greatest difficulties in obtaining an alteration in slum property was due to those immediately interested who were at the same time acting in a representative capacity on Town and City Councils. If sanitary officials throughout the country would only speak their minds, there is not the slightest doubt we should have an equally powerful indictment from them to the same effect. In paying a deserved compliment to the Manchester Corporation, the chairman complained that they did not move rapidly enough. But he explained that the Sanitary Committee was considerably hampered and restricted by the conditions under which they had to administer the law. But slum property, he pointed out, could be condemned and compulsorily closed, and that was the line which they proposed taking. The purchase of land, by compulsion if necessary, he advocated; but the building of houses for the people on the barrack system he deprecated. One of the Councillors, who moved a resolution urging the Local Authorities to use the powers they possessed under the Housing of the Working Classes Act, 1890, said that the difficulty which arose in clearing insanitary areas was that, in closing those houses, they brought about a condition of things generally worse than prevailed before. He also objected to barrack dwellings, but admitted that where such dwellings had been erected a healthier state of things existed. One noteworthy fact cited by the speaker was that there were no building bye-laws in operation locally to prevent builders constructing a house any size they liked, and the consequence was — much the same as it is in the suburban districts of London — that birdcages were built with a view of getting as much out of the transaction as possible with the least possible expenditure. The discussion which followed produced opinions more or less in harmony with the foregoing. One speaker believed that cheap exit from the crowded cities by means of electric power would help matters. Another advocated wholesale confiscation of insanitary property by the Government. The unification of building bye-laws throughout the country was also put forward. A Salford councillor aired the view that the land question was at the root of the housing question, and maintained that greater attention ought to be paid to the quality of the land upon which houses were built. When dwellings were built on rubbish and ashpit heaps it was no wonder that disease and deaths resulted. The taxation of ground values was supported by another councillor. A clergyman present expressed himself opposed to taking people out of the cities into the suburbs, as it only meant trans-

planting the evil thither. Another clergyman thought that if the poor could be got to take an interest in living a cleaner, healthier, and happier life, it would go a long way towards improving the housing of the people. The meeting did not, however, confine itself to mere speechifying, and the formation of a strong local Council resulted. From this and other signs, Manchester would seem to have put its hand to the plough in real earnest, and there must be no turning back. As one of the speakers said, the great drawback to reform is the apathy of those for whom the reform is intended. But there is equal danger in the apathy of those upon whom the duty of pressing home reform devolves. This is a truism that the advocates for housing reform must bear in mind. Apathy in mankind is like rust in machinery, it corrodes the best impulses and dulls ambition. Vigorous and sustained action alone will lead to the desired results.

Spread of Small-pox in Scotland.

The outbreak of small-pox in Scotland continues to spread, and to occasion grave concern to the Health Authorities. Cases are reported from a large number of districts, mostly in the western and central counties, but the wide range which the outbreak has attained can be appreciated from the fact that the disease has also appeared in places so widely separated as Dundee, Fifeshire, Morayshire, and Dumfriesshire. Everywhere the sanitary officials are exercising the utmost vigilance to check the further spread of the epidemic. A very large proportion of the cases in other districts can be traced to Glasgow, where, notwithstanding certain fluctuations in the returns from day to day, the increase in the number of cases has been steady. Dr. Chalmers' weekly return for the week ending last Friday showed 121 admissions to hospital, 51 dismissals, and 12 deaths. The number of cases in hospital was then 456, which was slightly lower than the number for the immediately preceding days. In the course of a discussion of the subject at a meeting of the Corporation, Mr. Dick, the Convener of the Public Health Committee, made an interesting statement as to the precautions adopted by the Sanitary Inspectors to preserve themselves from infection when visiting the small-pox wards and houses where infectious disease existed, the success of which was evidenced by the fact that during a period of twenty-five years no case was known of infection having been carried by the men to their own families. A petition by the Inspectors for extra remuneration for re-vaccination work came up at the same meeting, but Mr. Dick explained that the right to such extra payment was already recognised by the Health Committee. The request, it appears, had erroneously been incorporated in a petition for overtime pay in connection with the additional pressure occasioned by the presence of the plague in the city during the autumn.. This request for plague overtime was, after a warm debate, refused on the ground, we understand, that it was "ordinary overtime," a reason which hardly appears very satisfactory.

The Arsenic Scare.

The recent unfortunate experience of Manchester of the wholesale poisoning of people by arsenic in beer has made some persons all of a sudden most unduly nervous. Arsenic is now hunted for in every article of food and drink with a sedulousness that has not been known for years. But the search for the poison has been carried out in Paisley with apparently greater zeal than caution. Half a dozen prosecutions at the instance of the Local Authority were brought before the Sheriff Court last week, in which two firms of grocers, and four druggists—the latter comprising three doctors—were charged with selling ground borax which was alleged to contain arsenious acid. When the cases were called, however, the Fiscal asked leave to withdraw the complaints, as it had been discovered that the analyses were erroneous. It was a very unpleasant position for a prosecutor to find himself in. The solicitor for the respondents pointed out that the burgh analyst's results had been checked by other experts, and in every case in which they had an opportunity of checking the analysis they had found it to be wrong. In three of the cases submitted no arsenic could be discovered, and in a fourth there was only one-fifteenth part of the quantity of arsenic alleged in the certificate. It was undoubtedly a very serious error. The position of a public analyst is a most responsible one, seeing that his certificates are the foundation on which charges of a criminal character are based, entailing the gravest consequences. The evidence in the Manchester inquiry showed that there is considerable laxity on the part of some analysts in their conception of their functions. It is to be hoped that any tendency to looseness of practice in so vital a matter will be checked after the object-lesson afforded by Manchester.

Notification in Kilmarnock.

Very strained relations have sprung up between the Medical Officer of Health for Kilmarnock and the Public Health Committee, on account of the former's refusal to send to hospital certain cases, which had been notified as infectious, having given rise to complaints. Whatever may be the merits of the dispute, of which we have no knowledge, the Medical Officer's conduct appears to have been certainly indiscreet. In a strongly-worded letter to the Committee, he not only described local doctors as working the half-crown notification fee as far as they could—which might, of course, conceivably be true—but he also indulged in abuse of the Council in terms which can hardly be characterised as other than intemperate. We are all familiar with the weaknesses and occasional follies of Local Authorities, from the metropolis downward, and Medical Officers have often much to put up with at the hands of their civic masters "drest in a little brief authority." Still, a sarcastic allusion to the prayers in churches "that Magistrates and Coun-

cillors might be endowed with wisdom," is neither seemly nor wise. Controversy conducted in such a strain is hardly dignified, and it cannot fail to provoke resentment and personal ill-feeling where there was only friction before. The Kilmarnock Town Council have in this case decided to lay the whole matter before the Local Government Board, and ask them to send an expert to inquire. We trust the result will be to restore peace and harmony in their Public Health Department, for without these efficient administration is impossible.

A Sanatorium at Work.

So much has been written about what is going to be done on behalf of the sufferers from consumption that many may be under the impression that the past has been a blank in this respect. But we have before us a report of what has been done during the last four years in Canada, and it is so good that great hopes may be entertained of what may be done as experience accumulates. It would appear that the National Association opened its first sanatorium in the autumn of 1897, and during the first year 500 consumptives who applied for admittance were refused for want of accommodation, or because they were too poor to pay for the treatment. This fact alone shows how little is being done compared with what should be done for these people. This sanatorium is situated in the Muskoka district of Ontario, near the town of Gravenhurst. The buildings cost about 60,000 dols., and give accommodation to fifty patients. The annual reports show that remarkable success has attended this institution. Home treatment of consumption results in about 99 per cent. of the cases terminating fatally, while in the same climate sanatorium treatment gave the following result for the last three years in that class of patients that remained three months or over:—Of thirty received, six were in the incipient stages of the disease, sixteen were advanced, and eight were far advanced. The result was, four were discharged cured, eleven with disease arrested, seven much improved, six remained the same, and two failed. The report states that many more would have been cured had they remained longer. This great difference between the results of home and sanatorium treatment is therefore due, not to climate, but entirely to the course of treatment. In Muskoka that consists principally in living an outdoor life, and in eating an abundance of nourishing food. Patients are obliged to be outside from eight to fourteen hours a day in winter or summer. Their surroundings are attractive, and suitable recreation is encouraged in every possible way. The outdoor life promotes appetite, digestion, sleep, and tones up the general system. It produces good blood, and this is the great enemy of microbes and disease. Perfect ventilation of all sleeping apartments is also insisted on. During last summer the buildings were filled, and many patients lived in tents. These did quite as well, if not better, than the others, which again shows the value of pure air. It is quite evident if pure air and good food will cure consumption, it will usually prevent its development, and these are facts that the general public should appreciate.

Salt and Snow.

Controversy has been raging during the past week over the methods adopted for clearing away snow from the streets. The disposal by means of "salting" has come in for strong condemnation, but from none more stringently than by Dr. William Neale. In his opinion it is "an abomination and cruel practice, alike to animals and human beings. Many of the omnibus and tramcar companies, I believe, defend the use of salt on the ground that the evils of this deadly slush are less than the injuries and strains which the horses sustain from slipping in the snow. That undoubtedly is the case, but it does not alter the fact that the practice is in itself an evil, particularly as regards human beings. The foot of the horse is well protected by a thick pad. Nature is his bootmaker, and Nature's handiwork is sound and good. So much cannot always be said for the human bootmaker. Just think of the thousand of clerks and poor people who go to work in the metropolis every day, many of them wearing unsound boots, the soles of which are little better than brown paper. Think what happens when these unfortunate people have to wade through the wretched freezing mixture that is always to be found in the streets when there has been a heavy fall of snow, and remember that in the great majority of cases these people have to wear their boots throughout the day. The intense cold that this mixture of snow and salt produces undoubtedly lays the foundation of all sorts of ailments, such as chills, colds, influenza, and pneumonia. There is a general lowering of vitality, and whenever that happens a man is particularly liable to catch any disease that is going about. It is no exaggeration to say that whenever there is severe wintry weather in London many deaths may be laid at the door of this system of using salt to clear away the snow. I am bound to admit that I cannot suggest an alternative system which would be equally rapid and effectual, but what I would urge is this, that if it is necessary to use salt to cleanse the roads and pavements, the resulting slush should be removed as soon as the salt has done its work, instead of being left untouched, as it frequently is, for several days. If that were done the evils of the practice would be at any rate reduced, if not altogether removed."

Something wrong at Cape Town.

There appears to be other matters than the war occupying the attention of the people in Cape Town. Something is wrong with the drains, if we may judge rightly from a paragraph in the *South African Review*. After twitting the engineer on his anxiety to have his name on the Corporation cart, the writer goes on to say that if "Mr. Wynne Robert is to be indulged in this peculiar craze for

self-advertisement, and if he desires to earn immortal fame as a sanitary genius, why on earth doesn't he go the right way to work with regard to the underground drainage system of Cape Town City? The roadways and pavements are being perpetually pulled up and laid down again. While the excavations are proceeding, harmless ratepayers, who never annoy the Town House people except when they call to pay their taxes, are nearly shocked out of their senses by the frightful gaseous abominations which assail them should they pass within twenty yards of the prospecting operations. For a month or two the public were excessively inconvenienced by some mysterious work which was carried on at the foot of the Avenue and corner of Wale-street. The annoyance, however, was patiently borne in view of the prospect of better drains and no smells. But now that this job is finished, what is the result? Why, the effluvia is worse than ever, and the worshippers at St. George's Cathedral have to bear with an olfactory affliction which sadly disturbs their devotional sentiments. In the streets intersecting Adderley-street and St. George's-street, and the thoroughfares above these two arteries of traffic, the state of the drains and the management of the Sanitary Department must be exceedingly defective; and the wonder is that the death-rate is not higher, not only in the crowded residential parts of Cape Town, but in the business centres, where men and women have all day to breathe a fœtid atmosphere for which the Town Council is directly responsible, while the traction engine juggernauts ramble gaily along." This, taken in conjunction with the accounts given in private letters of the crowded nature of the district by those anxious to get into the Transvaal and neighbouring places, tends to the opinion that Cape Town is not at present one of the "Health Resorts of the universe."

Housing Problem in Hongkong.

Last week's mail brought with it a report of a special meeting of the Hongkong Sanitary Board, at which the general condition of the city was discussed. We have not space to give the details of the meeting, but what was said by the various speakers displayed a state of affairs calling for drastic measures of reform. Every phase of sanitary work requires developing in order to meet the growing population, which is fast outgrowing the district and creating a housing problem quite as acute as anything we have at home. One of the speakers asserted that it was common knowledge to every member of the Board how "appalling was the condition of rents in the colony." The poorer classes "are being literally robbed and squeezed out of their food and clothing in order to pay excessive rents. Floors which a year ago were rented at £6 now paid £19." The same causes that prevail at home have helped to bring about this condition. The workers must live near their employment, and the landlords take advantage of their position. Commenting on the discussion, the *Hongkong Telegraph* cites the case of a Portuguese clerk, residing in Kowloon, and who rented a floor at three dollars per month. His rent has been raised from time to time during the last two or three years, until he is now paying twenty dollars a month for the same accommodation for which he formerly paid three. Needless to say, his salary has *not* been increased by nearly 700 per cent. during the same period, and, as he is employed in Kowloon and is obliged to live there to be near his work, and is unable to find cheaper quarters, he consequently feels the pinch severely. It is the same with European houses. In 1898 a house was rented at forty-five dollars per month. When the year's lease expired the tenant was informed that he could keep the house on at seventy-five dollars. On his expostulating he was calmly informed that there were plenty of people willing to pay that rent, and he could either do so or vacate the house. We don't think that anything much worse than this can be found in London. But in Hongkong it is just as it is in the United Kingdom. All can point out the disease, but none can provide a remedy suitable to the case.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

It is extraordinary that Local Authorities should continue to manifest such incompetence in regard to dealing with snow after every fall. Some excuse may be given for their unpreparedness and consequent inability to deal with the first snowstorm of a season. But when a second and a third fall comes, and each time the Authority is in a hopeless muddle, and the footways and roadways are not cleared for some days, then a charge of incompetence against them is justifiable. And this is just what is being done, and rightly so, against many Authorities at the present time. I do not see how it is possible to avoid laying the blame on the Surveyor to the Authority. The public censure should be taken by him as appertaining to his department unless he can show that he is restricted as to expenditure, and this rarely happens. It may be taken for granted that I should not fasten the responsibility upon him unless I had very sufficient grounds for doing so. But it is to his ultimate good that I should be candid towards him. And the way in which numerous surveyors muddled through the task of clearing the roads in the most recent snowstorm was not worthy of them. I pointed out recently how in some districts the difficulty was met by clear-headed and capable surveyors who had prepared their programmes before winter set in, these programmes being printed and placed in the hands of all their foremen and sub-foremen, and who fell in to the work allotted them and cleared the roads with an alacrity which excited much favourable criticism. And what could be done in these districts could be done in all districts with the exercise of foresight, business capacity, and intelligent supervision.

I have observed that some surveyors allege that the cost of carting away snow from macadam roads, even in residential and business streets, is not justifiable, and that it should be left to disappear by the influence of the atmosphere—*i.e.*, by thawing. This opinion is one which cannot be supported, except as regards rural roads, where vehicular traffic is slight, or where a rapid thaw sets in. But when the snow is allowed to lie on the road for a number of days, as recently, and melting

is effected only under the sun's rays, the saturation of the road surface is so great as to transform it, under vehicular traffic, into a sea of puddle, and under such conditions the wear and tear upon the road is—I think every experienced surveyor will admit—incalculable, and the damage caused to it and cost of cleansing is greater than the cost of carting away the snow.

Municipal surveyors do not generally seem to be aware that they are prohibited under the Act of 1875 from receiving payment from their own Local Authority, for extra services rendered in the form of a percentage on the cost of work executed under them, as this constitutes an interest in a contract and is contrary to the provisions of Section 193 of the Act. It frequently happens that a surveyor is asked to undertake duties outside those prescribed at the time of his appointment, such as the preparation of plans for making up roads under the Private Street Works Act, 1892; or of important schemes of sewerage or water supply; or of architectural work, and for which extra duties his Authority are willing to pay him a commission on the cost of the work or amount of the contract. It should be generally known that a payment in this form, if received by the surveyor, may render him liable to the penalty of £50 and loss of office as provided by the section beforenamed. He should therefore ensure that his Authority's resolution protects him against possible proceedings for the recovery of the penalties, and that such resolution provides for a payment by a lump sum—equivalent it may be to that which would be earned if paid by commission. The well-known case of Whiteley *v.* Barley, where the local surveyor was successfully sued for the penalty of £50 and precluded from afterwards holding any office under the Act, should be borne in mind.

I MENTIONED some time ago that a new device for lighting incandescent burners in street lamps would be shortly put on the market. By this device the necessity of a pilot light is abolished, and the gas is lit with the torch-rod, but without the latter entering the lantern. Immediately under the lantern is constructed a small metal box, open at the bottom, containing a lever, which is lifted by the torch-rod, and allows the gas to enter a perforated copper tube which extends to the upper part of the mantle. The gas is ignited in this tube by the torch-rod, the flame runs up the tube, and also lights the burner. As the torch is withdrawn from the cylinder the lever falls of its own weight, shutting off the igniting gas. It is claimed that by its use a saving of one-third cube foot per hour of gas which is consumed by the pilot light is effected, that flap doors in the bottom of the lanterns may be abolished, whereby the lantern may be made wind, rain, and dust-proof; and that a great saving of mantles may be effected. The apparatus, the price of which is 10s., is the invention of one of the engineers of a large London gas company, is now obtainable from the well-known gas-lighting engineers, Messrs. H. Greene and Sons, 19, Farringdon-road, London, E.C., and is being already generally adopted in some districts, and I would advise those of my readers, who have control of street lighting to purchase a sample for a trial. SENEX.

AT a recent meeting of the Workshops Sub-committee of the Cleansing Committee of the Aberdeen Town Council, the proposed purchase of a refuse destructor was again considered. Several replies from towns where these destructors are already in use were read, and the Burgh Surveyor was instructed to issue a plan and a list of the conditions to be complied with to the various makers of destructors in the country, and to request them to send in offers.

REVIEWS.

"*Journal*" *of the Sanitary Institute.*—The *Journal* of the Sanitary Institute, just issued, contains a long article by Professor A. Celli, of Rome, on "Researches on the Propagation of Malaria and the Precautions to be Adopted in Unhealthy Districts." After describing some of the opinions of other investigators he gives reasons for deciding that the dappled winged gnat known as Anopheles is the propagating agent. He then describes the life history of the insect, and sets out a series of corollaries for the hydraulic engineer, for the sanitary engineer, and for the agriculturist, in which are detailed the steps that can be taken to prevent the multiplication of the Anopheles, and other measures against the spread of the disease. The concluding portion of the paper gives instructions for the self-protection of labourers in malarious places. The paper is illustrated from some of Professor Celli's photographs showing methods of protecting houses and shelters. The same *Journal* contains papers by Dr. Tidswell, Medical Officer of Health, Sydney, N.S.W., and Dr. Kaka, Medical Officer of Health, Karachi, India, on their personal experiences of the plague in Sydney and Karachi, with descriptions of the preventive measures adopted. Some microscopic photographs of the plague bacilli, and dissections of plague-infected rats and guinea pigs, appear in the paper.

National Health Society.

OFFICIAL TRANSACTIONS.

VOTE OF CONDOLENCE WITH H.R.H. PRINCESS CHRISTIAN.—At a special Committee meeting, held on Monday, February 4th, the following resolution was passed:—"The Committee of the National Health Society desire, in the name of the members, workers, and officials of the Society, to express their respectful sympathy with H.R.H. Princess Christian of Schleswig-Holstein, in the great sorrow which has befallen her Royal Highness by the death of the Queen." This resolution was immediately forwarded to H.R.H. Princess Christian, whose interest in the Society has always been so great, and whose recent kindness in becoming president will be remembered.

IT has been suggested to the Committee that a subscription list should be opened to raise a memorial to our late beloved Queen. The form the memorial shall take will be considered later, and must necessarily depend upon the amount received. It seems especially fitting that as the majority of the workers of the National Health Society are women, they should show their appreciation of the encouragement given to women by her Majesty throughout her reign.

EXAMINATION FOR THE DIPLOMA.—The first half of the examination for the diploma of the Society (Sanitation and Hygiene) was held by Dr. Louis Parkes at 53, Berners-street, W., on Friday, February 1st. Five ladies presented themselves for the examination, and all were successful in reaching the required standard. The names of the successful candidates are as follows:—Miss Georgina Bevan, Miss Irene Cox, Miss Gertrude Looker, Miss Edith Olliff, Miss Lucy Spiller.

HOMELY TALKS AT HOVE.—A course of "Homely Talks" on "Infant Management" is now being held by one of the Society's lady lecturers at Hove. For some time past annual courses on "Home Nursing" and "First Aid" have been given under the Hove

Technical Instruction Committee, so that the present subject is somewhat of a change. At the opening lecture the chair was taken by Alderman Henriques, who impressed upon the audience the vast importance of the subject before them. The instruction given is entirely of a practical nature, and much interest is taken by the audience in the teaching.

Lectures at Berners-street.—The fourth lecture of Sister Katharine's course on "Sick Nursing" will be given at 53, Berners-street on Thursday, February 14th, 3.30 p.m., the subject of the lecture being "Medical Nursing." Practical demonstrations on poultice making, &c., will be given. On Monday, February 18th, 3 p.m., Dr. Cantlie will give a lecture on "Insensibility," being part of his course of "First Aid" lectures at 53, Berners-street, W.

Public Works.

SEWERAGE.

The Kirkby-in-Ashfield Urban District Council is requiring a loan of £1000 for sewerage works.

The Romford Rural District Council has agreed to apply for sanction to borrow £2200 for drainage works.

A Local Government Board inquiry was held at Uttoxeter last week, with reference to an extensive scheme of sewerage and sewage disposal for that place.

Mr. H. P. Boulnois held an inquiry on behalf of the Local Government Board at West Hartlepool recently with reference to the proposal of the Town Council to borrow £26,500 for the second section of the new drainage scheme now in course of formation.

The Hartlepool Town Council has resolved that the Borough Engineer be instructed to proceed with the Whitby-street section of the sewerage scheme, that he have the specification printed and the plans lithographed, and that he afterwards advertise for tenders.

The partial opening of the new sewage works at Salterhebble, on the river Calder, constructed by the Halifax Corporation, took place last week. The site is at the junction of the Hebble Brook with the Calder, and when completed the scheme will cost £60,000.

We understand that the Local Government Board and the Board of Trade have approved of the scheme of sewerage and sewage disposal, prepared by Mr. E. J. Silcock, C.E., of Leeds, for the Rural District Council of Riccall. The works will be put in hand immediately.

At last week's meeting of the Llanelly Urban District Council it was decided to accept the recommendation of the Sanitary Committee to proceed with the Forge drainage scheme with the outfall at the Carmarthenshire Dock, subject to the approval of the Harbour Commissioners.

At Coventry County-court last week the Town Clerk applied for a further month's suspension of the sewage injunction granted against the Coventry Corporation to prevent a further pollution of the river Avon. Mr. Beard said the works were now practically complete. The works at the farm had been finished, and everything was prepared for pumping the sewage on the land. The engineers had twice inspected the river with a view to carrying out work for cleansing it, and their report was in course of preparation. At the end of the month he hoped to make an application for the discharge of the injunction. Mr. Passman, Clerk to the Warwick Rural District Council, said his Authority was satisfied that the end was nearly in sight, and as Mr. Beard's demand was very reasonable, he would offer no opposition. His Honour Judge Ingham granted the application.

At the last monthly meeting of the Colchester Town Council it was resolved to apply to the Local Government Board for sanction to borrow £10,000 for the extension of the sewerage outfall works, the construction of filter beds, and the provision of additional sludge plant; and, further, to borrow £9000 for the construction of new main sewers for the sewerage of St. Botolph's Valley and Maldon-road districts.

The Orsett Rural District Council has decided upon an extension of the Chadwell and Little Thurrock sewer to the docks, and Mr. S. I. Adams, F.S.I., has been instructed to at once prepare the necessary plans, sections, and estimates on the lines of the plan submitted by the Dock Company at a remuneration of 2½ per cent, inclusive of all charges, except quantities, and a further 2½ per cent. for supervision when the work should be proceeded with.

At a recent meeting of the Gorton Urban District Council the minutes recorded that at a special meeting of the Sewage Committee it had been resolved to apply to the Local Government Board for sanction to borrow £17,700 to cover the cost of further sewerage and sewage-disposal works within the district, £2750 to carry out certain works of surface water drainage, and an additional £3000 to defray the expenditure on sewerage and sewage-disposal works already completed. The minutes were confirmed.

At a recent meeting of the Water, Lighting, Drainage, and Cleansing Committees of the Dalry Council, a letter was submitted from Thomas Biggart and Co., Limited, Bridgend Mills, giving consent to the laying of sewer through their property on payment of wayleave. Messrs. Biggart made notification that in terms of the Rivers Pollution Act facilities should be afforded them for carrying the liquid discharges from their mills into the drainage sewer. This was granted. The contractor for the work is to lodge the sum of £500 as security.

There has been so much delay on the part of the Portsmouth Town Council in dealing with the defective system of drainage in Portsmouth, that it is satisfactory to note the Drainage and Sanitary Committee has at last decided to make an effort to successfully deal with the problem. The members have passed a resolution recommending the Council to approve the expenditure of £43,200 upon a relief sewer from Somers-road to Eastney, with the assurance that if adopted the scheme will minimise backflooding in certain parts of the town.

WATER.

The Holywell Rural District Council has resolved to proceed with the water supply of Bagillt.

The West Penwith Rural District Council has decided to take in hand the water supply of the parish of Gulval.

Last week a special meeting of Norden District Council was held at Norden, to formally sanction opposition to the Bill which is being promoted in Parliament by the Heywood and Middleton Water Board.

The Local Government Board inquiry into the proposed new regulations of the London water companies was opened on Monday last. Quite an array of counsel were present to guard the interests of the various authorities.

The Burgess Hill Water Company now have a Bill in Parliament, and the Cuckfield Rural Council wants to obtain a purchase clause in that Bill. The Burgess Hill Urban Council not approving of this move has asked the Chailey Rural Council to join it in a Water Board, but the Chailey Council is thinking of supplying its own district with water, so, while willing to help in preventing the design of the Cuckfield Authority, has offered only its "moral support" to the Burgess Hill Council.

THE Buckfastleigh District Council has approved the plans and estimates produced by Mr. Stainthorpe for carrying out the Lambsdown scheme, and has decided to apply to the Local Government Board for sanction to borrow the sum of £5500 for works of water supply.

A LOCAL Government Board inquiry has been held at Colchester with reference to an application by the Town Council to borrow £1800 for works of water supply, and £400 for the erection of cottages on the Severall's Estate. The larger sum is required for the laying of water mains to Old Heath.

THE Desborough Urban Council having decided to oppose the proposed Kettering Water Bill, a meeting of owners and ratepayers was held recently, for the purpose of taking into consideration and determine upon the expediency of consenting to the opposition to the proposed Bill on the part of the Council.

ALDERMAN ALF COOKE, presiding last week at a meeting of the Leeds City Waterworks Committee, reported that 2¾ miles of the new 30in. main from Swinsty to Eccup had been laid, out of a total length of twelve miles, and that the work of laying the high-level 18in. pumping main from Headingley to Bramley was progressing satisfactorily towards completion. He further stated that all the reservoirs in the Washburn Valley were full, and that they were capable of supplying the city for 118 days, as against 114 days at the corresponding period of last year. In Eccup reservoir there were 543 million gallons, with a depth of 41ft. 11in., as against 340 million gallons, with a depth of 35ft. 3in., last year. The total daily consumption, he added, was now 15½ million gallons, as compared with 15¼ million gallons last year.

MR. J. SHAW, President of the Surveyors' Institution, presided on Monday night over a meeting of its members at 12, George-street, Westminster, when a paper was discussed, which had been previously read by Mr. R. E. Middleton, on "The Future of the London Water Supply." Mr. W. Hunter said the true solution of the problem was first to develop and utilise the admirable supply which the natural position of London secured to its inhabitants. He held that the question of water supply ought to be treated on national lines, by which means the claims of all cities and towns and districts could be fairly determined. Whereas the total estimated cost of the Welsh scheme of the London County Council was £37,169,000, that of the Thames scheme, yielding an equal daily supply, was £17,486,000. Mr. Wheeler, K.C., contended that there was nothing whatever to justify the burden and expense of going to Wales for London's water supply at the present time. Mr. B. Ellis denied that Wales could yield an inexhaustible supply of water.

AT the Works Committee of Edinburgh Water Trust last week, the question of the Provisional Order now before Parliament was taken up. A statement in connection with this has been prepared for the Examiner of Committees of the House of Commons. The Committee approved that should the explanation prepared by the convener not be sufficient, the following should proceed to London to meet the Secretary of State for Scotland or the Chairman of Committees of both Houses: Lord Provost Steel, the convener; Mr. A. Archibald, Sir Andrew M'Donald, ex-Provost Wood, the Clerk, the treasurer, and the engineer. The Committee agreed to accept the estimate of Robert Laidlaw of £2530 for additional pipes. The engineer laid before the meeting copies of correspondence with the Peebles County Road Surveyor anent the widening of the bridge at Broughton, where the public road crosses the railway. The matter was remitted to the engineer. The Committee sanctioned the laying of a new pipe in Jeffrey-street.

THE Rochford Rural District Council has resolved to borrow £25,000 to complete the scheme of water supply for the western portion of the district, that sum being in addition to the £3000 already borrowed for the well at South Benfleet.

SHERIFF VARY CAMPBELL has refused to grant the petition presented by the Kelso Town Council under the Lands Clauses Act to compulsorily obtain a supply of water from springs on the farm of Ladyrig for the requirements of Maxwellheugh and the higher parts of the burgh. In a note, his lordship says the probability is that a steady supply would not be secured, and it was a case of penny wisdom. It is understood the Town Council has again approached the proprietors with a view to utilising the water for Maxwellheugh alone, but a section of the ratepayers are strongly opposed to the scheme.

THE Derwent Valley Water Board has deposited for the information of Parliament estimates prepared by its engineer showing the gross and net expenditure which will be incurred in the event of sanction being given to the proposals contained in its Bill for this session. The estimated gross expenditure of the proposed new works is put down at £703,000, of which the single line of railway from Hope Woodlands to Derwent will cost £19,315, and the other works, including the proposed new Derwent reservoir, £683,685. It is, however, estimated that the authorised works proposed to be abandoned, which include the already sanctioned Derwent reservoir, would have cost £441,000. The gross estimate is thus reduced to £262,000, which is the amount given by the engineer as the actual additional expenditure which will have to be met should the Bill receive the sanction of Parliament. To provide for this expenditure the Board will ask for £300,000 further borrowing powers, and "such further sums as may be necessary" to pay the cost of passing this Bill through Parliament, and for the payment of interest on this sum until the expiration of ten years "from the passing of the Act." The usual declaration has been made by the Clerk to the Board that the money required will be "raised upon the security of the revenue of the Board arising from the contributions of the four Corporations of Derby, Leicester, Nottingham, and Sheffield."

THE half-yearly meeting of the Chester Waterworks Company was held at Chester last week. The accounts for the half-year showed a surplus of revenue over expenditure of £2545, and adding a balance brought forward from the previous half-year (after payment of dividends) of £6759, made a total of £9304. The Chairman, in moving the adoption of the report, said, according to the statement of their engineer, the amount of water pumped and distributed during the year 1900 was upwards of 638 millions of gallons, being an increase of 16 millions on the previous year, and showing a daily supply of 36 gallons per head of the population. With regard to the water scare, there was generally such a scare once a year, and he had come to look upon them as good things. The cause of the recent scare was the rainy season, and not any inherent defect in the works. The water had improved very much, and Dr. Frankland, in his most recent report to the Public Health Committee, stated that the samples of filtered water both from the works and the consumers' tap were almost perfectly clear to the eye; they were palatable and contained only a moderate amount of organic matter. The efficiency of the filtration was indicated by the fact that out of every 100 bacteria present in the unfiltered water no fewer than 95 were removed in the process of filtration. The results, both bacteriologically and chemically, were much more satisfactory than on the occasion of his last quarter's examination. Dr. Boyce's most recent report was also very good, and showed that there was an almost absolute absence of anything deleterious.

The Bridgwater Rural District Council has approved of the new water scheme prepared by Mr. Markyn, the engineer, by which it is proposed to take the water, which is required for seven parishes, from springs on the Willoughby estate at Broomfield, the total cost of the scheme being estimated at £30,000.

Last week a meeting of the Lancaster ratepayers was held to consider what steps should be taken in the matter —whether an adequate supply should be provided for Galgate, or whether the householders, &c., were to go on as at present—obtain water from the wells and pumps in the village. It was finally decided to obtain a supply from Thirlmere.

LIGHTING.

The Eastbourne Town Council has made a net profit during the past year of over £300 on its electricity works.

The London County Council has agreed to lend £17,229 to the Hampstead Borough Council for an electric light installation.

The London County Council has decided to lend the St. Pancras Borough Council £830 for the electric lighting of public buildings.

The Conway Town Council has accepted the contract of Mr. R. Dempster for the extension of the gasworks, and for supplying plant, for £5130.

The Electric Lighting Committee of the Hereford Town Council has received the sanction of the Local Government Board to a loan of £5000.

The Newark Town Council has decided to make application to the Local Government Board for sanction to a loan of £30,000 for the purpose of adopting an electric lighting scheme.

The question whether or not Gravesend shall be lighted by electricity was thoroughly debated by the Town Council last week, and ultimately decided in the affirmative. In a report to the Council, Mr. W. H. Trentham, M.I., &c., stated that the cost of providing a generating station for lighting purposes only, including the mains and public lighting, would be £25,000. Working expenses would be £1936, interest and redemption £1438; making a total of £3374.

At the ordinary general meeting of the Chester United Gas Company held last week, the directors reported that after providing interest on loan capital and dividend on preference stocks, a profit remained of £3555, out of which it was decided to pay the statutory dividends on the ordinary stocks, carrying forward a small balance. Owing to the heavy increase in the cost of coals the company had increased the charge for gas 5d. per 1000 cubic feet, and during the quarter had paid over £3000 extra for coals.

The report of the engineer (Mr. George Wilkinson, M.I.M.E., Harrogate), appointed by the Otley District Council to report upon the question of the establishment of a public electricity supply for the town, has just been presented to the Council, and was last week considered by the Electric Lighting Committee of the Council. Mr. Wilkinson's proposals include the establishment of a steam-driven generating plant in a field near the river, capable of providing 6750 8-candle power lamps. He estimates the capital outlay at £18,000, and the annual expenditure at £1122 15s. The revenue is to be derived from the sale of current to 6750 lamps, at 6d. per unit, averaging 7s. per lamp per annum, a total of £2362 10s. Thus the annual gross profit is £1239 15s., and the net profit is estimated at £231 15s. In comparing this scheme with that for obtaining a supply in bulk from the Yorkshire Electric Supply Syndicate, he estimates the total annual expenditure for the latter at £2110 10s., and the receipts at £2250, thus giving a net annual profit in favour of local work of £92 5s.

The annual meeting of the shareholders of the Coatbridge Gas Company was held last week. The directors' report and balance-sheet were unanimously approved, and dividends at the rate of 10 per cent. per annum on the original stock and 7 per cent. on the new shares, 1877 and 1898 issues respectively, were declared. The chairman said the consumption of gas showed an increase of 3 per cent.

The Board of Trade gas returns recently issued, giving statistics for the year 1899, show that in the United Kingdom in that year there were 450 authorised undertakings in the hands of companies and 232 in the hands of Local Authorities, making a total of 682, an increase as compared with the previous year of twenty-one, of which eleven are company undertakings, and ten in the hands of Municipalities.

Col. Makins mentioned at the recent meeting of the Gas Light and Coke Company that the directors had to announce a deficit in the amount required for the statutory dividend to the extent of £71,000. This was due to the abnormal price of coal and the abnormally mild weather, especially during the month of December. He could promise no alleviation in these adverse factors during the current half-year. There could be no reduction in the price of gas, and consequently no increase in the rate of dividend. Looking beyond June 30th the prospect was more satisfactory.

The deputation from Edinburgh, which visited London, Bolton, Oldham, and Brighton last Thursday, reported that the system of providing cooling towers and condensing plant at the electric lighting stations would not be tolerated in Edinburgh. In some places the steam was so great that the deputation had to put up their umbrellas to protect themselves, and as at Macdonald-road the nuisance would be several times multiplied, they recommended that there should be no cooling towers or condensing plant introduced there, but that the waste steam should be sent up an iron pipe at the top of the chimney.

A deputation from the promoters of the Electric Power (Yorkshire) Bill attended before the Sub-committee of the Parliamentary Committee last week, and inquired whether the Sub-committee would recommend the Council to support the Bill. The proposed area of supply of the company comprises that part of Yorkshire lying to the south of the river Aire, and is practically the whole of the West Riding. Some discussion took place on the provisions of the Bill, and when the deputation had retired the Committee resolved to recommend the Council to present a petition against the Bill unless the promoters would exclude the city of Sheffield from its operations. The Sub-committee was, however, perfectly willing to agree to a clause being inserted, authorising the company and Corporation to make an agreement for the supply of electricity in bulk to the Corporation if it should require it.

GENERAL.

The St. Ives (Cornwall) Town Council has decided to erect new slaughter-houses.

The Acton Urban District Council proposes erecting public baths at a cost of £18,000.

The Hammersmith Borough Council will receive the loan of £2200 for an underground convenience.

An underground convenience is to be constructed in Queen's-square, Wolverhampton, at an estimated cost of £2400.

Another case of small-pox has been reported to the Bradford Medical Officer from the Wyke district. There are now seventeen patients in the hospital at Bierley, but it is not anticipated any case will terminate fatally. Quite two-thirds of the sufferers are from Wyke, and they are all restricted to relatives and neighbours.

The London County Council has agreed to lend the Hackney Borough Council £9750 for street improvement and paving works.

The London County Council has decided to lend £24,145 to the Fulham Borough Council for a dust destructor and electric lighting.

Dr. R. Dudfield, Medical Officer of Health for Paddington, reports that for some years past no infectious sickness has occurred among those living on the canal boats working to and from Paddington.

The Municipal Authorities at Leicester have just opened a large extension of their lunatic asylum accommodation, at a cost of over £100,300. The work was necessitated by the steady growth of lunacy in Leicester.

The new cart-and-pail sanitary system, recently contracted for by the Pietermaritzburg Town Council, provides for the acquisition of five sanitary carts and gear, four galvanised iron slop carts, 7000 night-soil pans, and various tools.

A Local Government Board inquiry has been held at Fareham with reference to the application of the Fareham Urban District Council to borrow £450 for the purchase of a site for an infectious diseases hospital for Fareham.

The outbreak of small-pox in Scotland is becoming serious, for it is reported rife in centres removed over a hundred miles from Glasgow. In Glasgow itself there are twenty-four new cases, making 436 cases in all; but the alarming feature is in the outbreak at Dundee, where ten cases have been found. Six have been discovered at Falkirk. The disease shows an increase at Coatbridge, Airdrie, and Paisley.

The Queenstown Sanitary Authorities have decided that, with a view to the prevention of the introduction of small-pox into Queenstown, Cork, or the South of Ireland, all ships and steamers arriving at Queenstown from Glasgow shall be subject to the regulations in force during the existence of the plague, viz., that the Medical Officer of the port shall visit all such vessels and inspect the crews and passengers on board before *pratique* is granted.

At a recent meeting of the Ilkley District Council it was reported that, in response to an application for power to purchase land for the purpose of a refuse tip, the Local Government Board had replied that it would be preferable for the Council to provide a destructor, and as it seemed that it was only proposed to tip the refuse on the land which it was desired to purchase as a temporary measure, the Local Government Board requested the Local Authority to reconsider the matter. It was decided to reply that considerable difficulty had been experienced in trying to obtain land for a destructor, and that the purchase of this land was the speediest way out of a pressing difficulty.

At the next meeting of the London County Council the Public Health Committee will seek authority to spend £50,000 on measures of precaution against plague. For the purpose of isolating "contact" and "suspected" cases, London is to be divided into four divisions with accommodation for both classes in each. Premises are to be fitted up for use as isolation homes at a moment's notice—that is to say, they will be stored with food, clothing, and the necessary appliances. Preparations will also be made for (1) further accommodation that could be got ready in a few hours; and (2) still further accommodation that could be got ready in a few weeks. The £50,000 will cover all cost in connection with 1000 "contact" cases and 100 "suspected" cases. Cases of pneumonic plague—a highly infectious and very fatal type—have recently occurred in Hull. "These cases," say the Committee, "following so soon upon the cases of bubonic plague at Glasgow, emphasise the importance of taking every precaution against the disease in London."

The Health Committee of the Sheffield Corporation has had before it tenders for the erection of a new destructor in Penistone-road, and it was agreed to recommend the Council to accept a contract for £33,000.

The Town Clerk of Crewe has received a communication from the Light Railway Commissioners, stating that they had decided to refuse to sanction the Council's request to borrow money for the laying down of electric railways in the borough and surrounding districts.

The Leicester Town Council has unanimously decided to purchase the undertaking of the Tramways Company and work it under its statutory municipal powers, and supersede the present horse power by electric traction. Roughly estimated, the cost of the scheme is over half a million.

The Baths and Washhouses Committee of the Islington Council reports that in order to complete the artesian well installation at Hornsey-road Baths authorised by the late Vestry it would be necessary to have additional steam and exhaust pipes, hot well, donkey pump, iron ladder to wells, and that Messrs. C. Isler and Co., the artesian well engineers, had agreed to provide this additional machinery and plant for a net sum of £241 10s. It would be also necessary to fence round the wells and machinery at an estimated cost of £30, and this with an allowance of £23 10s. for contingencies, would bring the total cost of this additional work to £285. The expenditure was approved by the Council.

On Tuesday next the London County Council will be asked to approve two large estimates for the conversion of the tramway system from horse to electric traction, one sum of £145,000, another of £478,000. The first is for buildings and a railway siding, and in this case repayment may be spread over sixty years. The second is for lines, machinery, generating plant, rolling-stock, and electrical equipment, the sum being repayable in twenty-five years. It is proposed to construct a generating station of sufficient capacity to supply electric energy for all the Council's South London tramways; but at present only the following lines are to be adapted (for the underground conduit system):—Those (*a*) between Westminster Bridge-road and Upper Tooting-road, (*b*) between Kennington Park-road (at its junction with Kennington-road) and the terminus at Blackfriars-road, and (*c*) between St. George's Circus and the terminus in Waterloo-road.

We alluded, says a Leicester paper, to the ways of diphtheria last week as past finding out. But the latest return of the Medical Officer shows that the bewilderment must be extended to the entire public health. The latest figures are, indeed, nothing if not paradoxical. On the one hand, we find that local mortality has tumbled down from 68 to only 41, or by no less than 27, at a swoop. On the other we are confronted by a leap from 16 to 26 in the fresh notifications of diphtheria. One consequence is that Leicester—according to the Registrar-General—runs Burnley closely for the blue riband, as returning the smallest death-rate of any large centre in the kingdom, our proportion being 10·2, as compared with the minimum of exactly 10. Another is that the borough once again figures, nevertheless, as being still in the midst of its now long-protracted epidemic of diphtheria. Even this, however, must be by no means alarming, seeing that it does not prevent Leicester from registering only two deaths to every three recorded even in the "Queen of Watering Places"—Brighton. What is the key to the remarkable decline in the death-rate, side by side with another leap in the epidemic? Several may be suggested. The more probable is the tale told by the fact that the deaths from pulmonary diseases and consumption fell during the past two weeks from no fewer than 21 to only nine.

The Worcestershire County Council has set on foot a movement to establish a hospital in the county for the open-air treatment of consumption, and it is thought Lickey Hall would be a suitable site. A conference was held at Worcester on Saturday, and it was decided to invite the co-operation of all the Poor Law and Sanitary Authorities. A large and representative Committee was appointed to take steps in the matter.

Last week, in submitting the estimates of the Hull Sanitary Committee for the coming year, the Chairman observed that they were the highest submitted to the Committee during his experience; in fact, he did not think there ever had been any bigger estimates. They included an item of £15,562 for night-soil and dry-dust collection, &c. The wonderful growth of the city necessitated the best sanitary arrangements, and he pointed out that 1643 new houses were erected in Hull last year. The total amount of the estimates was £30,380, and it would therefore be seen that the night-soil collection was responsible for more than one-half of that amount. Hospitals were put down at £7426, and it would be seen from the particulars that that was by no means an excessive charge. The balance was made up of eleven items, and they were told that they could not do with less money if the work was to be carried on efficiently. With a rateable value of nearly £1,000,000 he did not think £30,380 was too much to spend on sanitary matters. The Committee finally agreed upon estimates amounting to £31,484, instead of £30,380 as originally proposed. The estimate last year was £26,199, but the actual expenditure amounted to £31,991.

PERSONAL.

Dr. Milner has been reappointed Medical Officer of Health for Lostwithiel.

Dr. Donald M'Donald has been appointed Sanitary Inspector for Kintyre, N.B.

Dr. South has been appointed Medical Officer for the Wimborne district of the County of Dorset.

Mr. H. R. Smith, of Plymouth, has been appointed third Sanitary Inspector to the Torquay Town Council.

Mr. W. Curry, of Droylsden, Lancashire, has been appointed Surveyor for the Urban District of Spennymoor.

Dr. G. F. Easton has been reappointed Medical Officer of Health for Alnwick, at a salary of £50 per annum.

Mr. J. Sloan, of Hetton-le-hole, has been appointed Drainage Inspector to the Town Council of South Shields.

It is proposed to increase the salary of Dr. Evans as Medical Officer of Health for Bradford, from £500 to £600 per annum.

Dr. E. G. Annis, Medical Officer of Health for Huddersfield, has been appointed Medical Officer for the Borough of Greenwich.

Mr. George Wallace, Surveyor to the late St. Giles' Board of Works, has been appointed Borough Surveyor to the Holborn Borough.

Dr. Turner, the newly appointed Health Officer for Bombay, left England in the India on the 30th ult., and will enter upon his duties in the middle of the present month. Mr. W. Maughan, Associate Member of the Institute of Civil Engineers, who has recently been appointed Deputy Executive Engineer for Drainage, ordinary branch, will arrive at the end of the month. Mr. Maughan, who was selected from about sixty applicants, has been for eight years in the office of Mr. Santo Crimp, and has been engaged on Mr. Crimp's atest drainage schemes as Resident Engineer.

Mr. W. A. Tester, of Plymouth, has been appointed Tramways and Electrical Engineer for Lancaster at a salary of £300 per annum.

Dr. Caldwell Smith has been appointed Medical Officer of Health for the Borough of Wandsworth at a salary of £800 per annum.

The salary of Commander Wells, the chief officer of the London County Council Fire Brigade, has been increased from £900 to £1000 a year.

Dr. Richard King Brown, of Old Kent-road, has been appointed Medical Officer of Health for the Borough of Bermondsey, at a salary of £500 per annum.

Dr. H. Poole-Berry has been reappointed Medical Officer of Health for Grantham, at a salary of £50, and Mr. James Barnacle, Inspector of Nuisances, at a salary of £45.

Mr. W. A. Collins, of Leyton, has been appointed Inspector of Nuisances for the Bridgwater rural district, at a salary of £140 per annum, in room of Mr. Wm. Coles, resigned through ill health.

Mr. Frank White has been appointed senior Sanitary Inspector to the County Borough of Northampton at a commencing salary of £140 per annum, subject to the approval of the Local Government Board.

Dr. Harris, Medical Officer of Health for the Borough of Islington, is, we understand, a candidate for the vacant post of Medical Officer of Health to the City of London. Dr. Harris has been in his present position about eight years, and has proved himself a most efficient officer.

Mr. J. H. Rider has been appointed electrical engineer of the London County Council at a salary of £1000 per annum. Mr. Riding is at present chief consulting and resident engineer for electric tramways and electric lighting under the Plymouth Corporation. Twenty-five gentlemen applied to the Council for the position.

Mr. Samuel George Burgess, secretary and manager to the Middle Class Dwellings Company, Rowton Houses (Limited), and Wharncliffe Dwellings Company, Limited, was on Tuesday appointed manager of the new Housing Department of the London County Council. The salary in this case has been fixed at £800 a year. There were 117 candidates for the post.

LAW CASES.

Power of Sanitary Officials to Enter Suspected Premises.

The Turriff District Committee of the county of Aberdeen recently raised an action in the Sheriff Court at Aberdeen against Alexander M'Gregor, as the owner and occupier of a dwelling-house in the village of Cuminestown, craving the Court to ordain the defender to admit the pursuers' servants, Dr. James P. Watt, Medical Officer of Health, and Archibald Bell Findlay, Sanitary Inspector, into his premises for the purpose of inspecting the same, and, in the event of the defender failing or refusing to obey such order, to grant warrant to pursuers' servants to enter by force into the premises, and to find the defendant liable in expenses. The petition proceeded on the averments that pursuers believed on reasonable grounds that there existed in said house a nuisance under the Public Health Act, namely, that the house was in a filthy and unwholesome condition, as well as the bedding, clothing, and articles of furniture therein; and that the Sanitary Inspector, along with the police constable, had applied for admission and been refused.

The Sheriff, before granting the order craved, ordered intimation of the petition to the defender, who appeared

by an agent and opposed the application as irrelevant in respect that it was not stated that the premises were believed to be injurious or dangerous to health, or a nuisance to his neighbours, and that they must be one or the other. Sheriff Robertson sustained this objection, but allowed the pursuers to amend the petition to the effect of stating that the premises were injurious or dangerous to health. The pursuers amended accordingly, and the Sheriff then granted the order. On inspection of the premises by Dr. Watt, it was found that no nuisance existed, and the defender thereupon moved the Sheriff to award expenses in his favour. The Sheriff-substitute made avizandum on the question, and has now found the defender entitled to his expenses. The following is his Lorship's note:—I take the broad facts: (1) That expenses were asked against him in the petition, and that, unless he had appeared, they would have of necessity been awarded against him; (2) that the petition was, in my opinion, irrelevant until it was by leave, amended; and (3) that the application has, after all, been found to be unnecessary and baseless, as, on inspection, there was found to be nothing in the condition of the house justifying interference. In these circumstances, and without laying down any rule, I think the defender should have his expenses.

Chemists and the Foods and Drugs Act.

IMPORTANT JUDGMENT ON APPEAL.

Mr. Justice Bruce and Mr. Justice Phillimore, sitting last week as a Divisional Court in the King's Bench Division, gave judgment in the case of Dickins *v.* Randerson, which had been argued previously, this being an appeal by a chemist at Skipton against a conviction by the West Riding Justices for selling mercury ointment not of the nature, substance, and quality demanded by the respondent, who is an Inspector under the Sale of Foods and Drugs Act, 1875.

Mr. Justice Phillimore, in delivering the judgment of the Court, said they thought the conviction must stand. Appellant sold mercury ointment, a drug which was called by that name in the "British Pharmacopœia," and having a certain fixed ratio of mercury. When he was asked for mercury ointment he ought to have sold the drug as prescribed in the "British Pharmacopœia," or if he was going to sell, what he, in fact, did sell—an ointment in which the mercury was only about a quarter of the standard strength, he should have explained that he was selling a weaker or diluted drug, and have so named it. He acted from no sordid motive, but none the less he was in the habit of selling to his customers something which was not of the nature, substance, and quality which they must be taken to have demanded.

It was said he sold the mercury ointment of commerce, and that there was a difference between that and the standard in the British Pharmacopœia. The apellant failed altogether to prove that, and did not even attempt to prove it. What he did attempt to prove was that there were two commercial standards of wide difference, a thing in itself unreasonable, and that he kept both standards in his shop, and sold one standard or the other, according as customers did or did not bring a prescription from a medical man. He might almost as well keep two weights or two measures. The practical mischief of such a practice was pointed out during the argument. If there were any danger on the other side it was avoided by the simple expedient of distinguishing the two drugs by calling the strong ointment mercury ointment, and the diluted ointment mercury ointment weak or diluted, and by recommending the latter to any customer whom he might think unskilled, or likely to use the drug in a dangerous manner. The cases quoted established the fact that if a drug was found in the British Pharmacopœia, and that drug was asked for, must be supplied, and if it was not sold with its ingredients in the proportions prescribed by the British Pharmacopœia there was at least *primâ facie* evidence that what was sold was not of the nature, substance, and quality demanded.

It was argued for the appellant that as the drug in question was a compounded drug, proceedings ought not to be taken under the 6th Section of the Sale of Foods and Drugs Act, but under the 7th Section, and for this purpose some observations of Mr. Justice Wright in Houghton *v.* Taplin had been invoked. The Court thought those observations had been misunderstood. At any rate this was clear, that a compounded drug was none the less a drug, and their Lordships thought that proceedings could be taken under Section 6, though they might also be laid in the case of a compounded drug under Section 7. They entertained no doubt that the appellant sold to the prejudice of the purchaser a drug which was not of the nature, substance, and quality of the article demanded by the purchaser, and so contravened the provisions of the earlier part of Section 6. The difficulty they had felt arose from the provision that such an offence should not be deemed to be an offence under that section where a drug was compounded as in the Act mentioned. It was argued for the appellant that because the article in question was a compounded drug, the sale of it came within the exceptions in Sub-section 3 of Section 6, and constituted an offence not under the Section 6 but under Section 7. The Court thought it constituted an offence under Section 7, and also under Section 6. The exceptions in Sub-section 3 of Section 6 did not apply to all compounded drugs, but only to drugs compounded as in the Act mentioned. It was very difficult to understand the meaning of the words "as in the Act mentioned," as they could find no provision in the Act to which those words would apply; but it seemed impossible to reject the word. They could not read the exceptions in Sub-section 3 as if they were not qualified by the concluding words, although it was difficult to say what was the exact meaning of the words. This, they thought, was clear, that no possible meaning could be given to the words that could apply to the article in the present case. It was certainly not compounded as in the Act mentioned, and the sale of it, therefore, did not fall within the exceptions mentioned. The appeal must therefore be dismissed with costs.

Judgment was entered accordingly.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2089.—Bye-laws as to Air Space do not Apply to Old Buildings.—"Surveyor" writes:—"An owner of certain dwelling-houses erected about 1810 is desirous of constructing a small workshop at the rear of his premises. Will you kindly say whether the proposed erection contravenes the bye-laws as to air space? The Model Bye-laws are in force in this district. (2) An owner has erected a green-house at the rear of his premises from his first floor. Does this contravene the bye-laws as to air space? The house was erected prior to the date of Building Bye-laws coming into force in the district? Would the owner be also able to erect a wash-house in his yard?"

Answer.—The Local Authority are not enabled to disapprove the plan on the ground that the proposed building reduces the air space of buildings erected prior to the adoption of Building Bye-laws in the district. The workshop is not a domestic building, and the clauses as to providing air space at the rear of such buildings do not apply. Plans must, however, be submitted to the Local Authority of the proposed building. (2) The Local Authority can enforce the submission of plans for the erection of such a building. They could not, however, refuse approval thereof on the ground that the air space was encroached on, as the existing bye-laws do not apply to houses built prior to their

DRINK PURE WATER

Physicians say 95 % of our countrymen and women fill their system with poison, lime, acid, minerals, old age matter, contained in raw water. Debility, nervous afflictions, skin and blood diseases, malaria, typhoid fever, are often the direct result of drinking impure water.

THE **'GEM'** PURE-WATER STILL is a perfect, hygienic, automatic apparatus, which will make the foulest water clear and sparkling, and remove all mud, lime, sewerage, microbes, and poisons. It is better than the most expensive filter, and should be used by all who value health. Send for pamphlet containing valuable information, or order a Still at once. AGENTS WANTED.

Call and see it in operation.

SANITARY INSPECTORS' EXAMINATIONS.

THOROUGH TRAINING BY CORRESPONDENCE

For above by an Associate of Sanitary Institute and holder of Sanitary Association of Scotland Certificate.—Write particulars and testimonials, N. W. H., "Malabar," New Eltham, S.E.

SANITARY ASSOCIATION OF SCOTLAND.

EXAMINATIONS IN SANITARY SCIENCE.

Examinations for Certificates of Competency in Sanitary Science are held each year as follows, viz.:—In Glasgow in April, in Edinburgh in October, and at such other time and place as the Board of Examiners may determine.

Entrance Fee £2 2s.

For further particulars apply to

GEORGE MIDDLETON, M.A., LL.B.,
Writer, 83, Bath Street, Glasgow,
Secretary to the Board of Examiners.

A Stamped Addressed Envelope must accompany all letters requiring an answer

SANITARY INSTITUTE EXAMINATIONS.

SPECIAL CORRESPONDING CLASSES

For the **Practical Sanitary Science,** and **Sanitary Inspectors' Examinations** of the **Sanitary Institute** and other Institutions, **1899 and 1900,** conducted by Sanitary Engineer and Surveyor, holding three certificates from the Sanitary Institute, First-class Honour Medallist Hygiene, &c. Hundreds of successes.—For all particulars, testimonials, &c., apply "MEM. SAN. INST." 28, Victoria-street, Westminster, S.W.

SELECTED WORKS ON
PUBLIC HEALTH

PUBLISHED BY THE

SANITARY PUBLISHING CO., LTD.

The Purification of Sewage and Water.
By W. J. DIBDIN, F.I.C., F.C.S. With numerous Illustrations and Diagrams. Second Edition. Price 21s. net.

The Removal and Disposal of Town Refuse.
By WILLIAM H. MAXWELL, Assoc. M. Inst. C.E., Borough Surveyor and Waterworks Engineer, Tunbridge Wells. Price 15s. net.

Disinfection and Disinfectants.
By S. RIDEAL, D.Sc. (Lond.). Second Edition. Price 12s. 6d.

House Drainage and Sanitary Fitments.

adoption. The owner may erect a wash-house on the air space, but he must obtain approval of his plans by the Local Authority before doing so.

2090.—Sewage Disposal Scheme: Power to Raise Money to Defray Cost.—"Engineer" writes:—"We have prepared a sewage disposal scheme which consists largely in alteration to old work. There is no land whatever provided and none available without pumping. Will the Local Government Board be likely to approve the scheme? If they refuse to approve it, would the Council be able to carry out the work by levying a rate instead of borrowing the money?"

Answer. — The Local Government Board do not approve schemes for sewage disposal and treatment unless the effluent is passed over land before being discharged into a stream. The Council may, however, defray the cost out of revenue, or they may in the alternative, where they are possessed of land for the purpose of sewage disposal, borrow any moneys on the credit of such land, and utilise the money so obtained to defray the cost of carrying out any work which they are empowered to do under the Public Health Act—see Sec. 235 of the Act of 1875. This power is free from the control of the Local Government Board.

2091.—Smoke Nuisance: Not Necessary to Specify Work Required.—"X. Y. Z." writes:—"There is a serious nuisance from a large metal works using steam boilers and muffles or annealing ovens. The proprietors set the Council at defiance, claiming exemption under Sec. 334 Public Health Act, 1875. The works are of such a nature as to make it difficult, if not impossible, for any but a skilled engineer to say for certain the actual cause of nuisance, bad construction or negligence, or to advise generally or specially as to remedies. The Inspector advises the Council to take the advice of an engineer or specialist in this class of work. The Clerk avoids the responsibility of advising by taking the opinion of counsel, who advises service of notice to abate the nuisance within seven days. He says that it is necessary to specify on notice the cause of nuisance, or to describe works to be done, or to call any evidence on any point except as to time of emission of black smoke. I advise the Council that under such conditions the prosecution will fail. What do you think?"

Answer.—It does not appear to be necessary in a case of smoke nuisance that the Local Authority should specify what works have to be done to abate the alleged nuisance. In Millard *v.* Wastall, Q.B.D., 62 J.P., 135, where the Ramsgate Urban Sanitary Authority had served a notice upon the occupier, Wastall, to abate a nuisance caused by the emission of black smoke from a factory chimney without specifying the remedy for the abatement of the nuisance, but merely "to abstain at all times hereafter from doing or suffering to be done anything which shall cause the said chimney to send forth black smoke in such quantity as to be a nuisance," and the magistrates dismissed the complaint on the ground that the notice did not specify the works required to be done in order to abate the alleged nuisance, it was held on appeal by Day and Lawrence, J.J., "that it is not necessary for the Local Authority to invent works to be done by the persons by whom nuisances are required to be abated. In many cases such as the present no works are necessary, all that is required is that the defendant should refrain from using such coal as caused the emission of black smoke from his chimney, which was the nuisance complained of. It is much the same as if a nuisance were caused by keeping pigs, the owners must either keep the styes clean or remove the pigs."

2092.—Plumbers' Registration Movement.—"C. A." writes:—"Being a plumber and interested in above movement, can you give me the address of the Secretary of the Sheffield Registration Committees, or could you give me the address of the central Society? There seems to be very little publicity given to the affairs of the company in regard to the movement, and no one appears to know the proper quarter to which to write."

Answer.—We agree with our correspondent that it is difficult to ascertain the particulars required as to registration of plumbers, &c., and we think the company should take some steps to bring to the notice of persons interested their address, which is, The Worshipful Company of Plumbers, 1, Adelaide-buildings, London Bridge, London, E.C. We have several other communications on the same subject from plumbers and others. The secretary will furnish information as to when and where examinations are to be held, and the syllabus of subjects for the examination.

2093. — Carbolic Acid: Sale of, Order in Council. — "M. O. P." writes:—"It is the custom of this Local Authority to supply carbolic acid free to occupants of houses where cases of infectious disease occur. The Inspector has a store of carbolic acid in 8 oz. bottles. Also a cask of crude acid. Will this practice, if continued, be contrary to the new order regulating the sale of carbolic acid?"

Answer.—The order only applies to the sale, and not to the gratuitous distribution of carbolic acid, and does not affect the free distribution of the poison by Sanitary Authorities. It is, however, advisable for Sanitary Authorities to label each bottle with the word "Poisonous," and such bottles should be of special shape, as prescribed by the order, and bear a notification that the contents are not for internal application.

TUBERCULOSIS—INFECTION, HEREDITY, PREVENTION, HYGIENIC TREATMENT.

By A. G. Young, M.D., Secretary State Board of Health, Maine, U.S.A.[1]

(*Continued from page* 140.)

The children of tubercular homes.—Children in homes where there are cases of consumption, particularly children in the first months of life, are especially subject to the danger of infection, both on account of their feeble power of resistance, and for other reasons now to be mentioned.

The bacilli of tuberculosis, like other bacteria, are forms of particulate matter, and, obeying the law of gravitation in common with other matter, fall toward the earth when unsupported. The gravitation of the bacteria in a room, towards the floor, especially in still air, is more rapid than might be supposed.

Neumann found in the Moabit hospital near Berlin, between half-past seven and eight in the morning, very soon after the patients had left their beds and the wards had been swept, from eighty to one hundred and-forty germs in ten litres of air. At nine o'clock the number had sunk to sixty-eight; between ten and twelve o'clock the number ranged from twenty-two to forty-two; in the early part of the afternoon about twenty. At night, from an hour and a-half to two hours after the patients had gone to bed and the ward had become quiet, there were only from four to thirteen germs in each ten litres of air.

According to Stern, after the dust had been disturbed in a room, and the room is again closed up, the greater part of the bacteria have fallen to the floor in from twenty to thirty minutes. After from one to two hours the air still contains a very few bacteria; leaving the room closed and undisturbed still longer, the air is found almost entirely free from germs.

Thus it results that, in rooms infected with dried tuberculous sputum, the floor serves as the lodging place for the larger part of the infective agent, and before complete subsidence has occurred the stratum of air near the floor contains a much larger proportion of the infection than does any other part of the air of the room. The breathing line of the young child, while on his feet, or on his hands and knees, is lower than that of older persons. When, therefore, there is danger of respiratory infection, the child receives a proportionally larger dose of it than does his elders. An added danger threatens the creeping child on account of its inclination to thrust everything into its mouth. His chubby little hand, moistened with his own saliva, sweeps the bacilli from the floor and returns to his mouth. The pathologic result is the frequent occurrence in these tubercular homes of the protean forms of tuberculosis—tuberculosis of the lungs, of the intestinal tract, and the mesenteric glands, of the cerebral membranes, of the bones, "scrofula," &c. As the recognition of many cases of tuberculosis among children is not easy, the actual number of deaths from tubercular infection exceeds considerably the number shown by any registration system.

In the State of Maine during the seven years 1892-98, there were 442 deaths from "cerebral" tuberculosis. Of those deaths 283 were of children under five years of age. There were also 1869 deaths from "inflammation" of the brain or "its membranes," 1113 of which were of children under five years of age. Many of these 1113 deaths undoubtedly were due to tubercular meningitis.

There were also registered in the same seven years 2522 deaths from "ill-defined diseases of infancy," 406 from atrophy and inanition, 655 from "debility and exhaustion," 292 from "anæmia," and 3761 from the "diarrhœal diseases of infancy." A correct diagnosis would have placed many of these under the various forms of tuberculosis as the cause of death.

Dr. W. H. Chapin,[19] of Springfield, Massachusetts, has made a careful and extended study of tuberculosis in that city. The following are a few of his family histories, which show the frequency of obscure brain affections in tubercular houses.

For instance, in the L. family there was in January, 1871, a death from consumption, and no more until 1879, when there was a child six months old died from marasmus; but two years later, in 1881, a person died of consumption again. The same year, two months later, another child died of marasmus. In 1884 there was a case of convulsions.

Another family history began in 1875. They had deaths in 1875, 1878, 1879, and 1881. The first was from hydrocephalus, the next from convulsions. The third was an uncle of the preceding two, and he died from consumption. The fourth was an aunt, and she died from consumption. The fifth was a child, and died from meningitis about four months later than the last case of consumption. They inherited their tuberculosis from the aunt who lived in the family! The mother and father are still living, and are not tuberculous.

Another family, in 1878, 1879, 1880, and 1883, had deaths as follows: The first from consumption, the second from tubercular meningitis, the third from consumption, and the fourth from convulsions.

Another family in 1871 had a death from consumption. That was the grandfather. In 1876 there was a case of death from convulsions, a child only one year old died five years later than the grandfather did. It may have inherited convulsions from the grandfather, but just two months later the father died from consumption.

Another family began in 1870. In March, 1870, there was a child three years old who died of meningitis, in 1871 another one, two months old, died of cerebral congestion, and in July, 1873, one died of cerebro-spinal meningitis. While those cases were going on, the father was actually tubercular; but he afterwards recovered.

Here is a family which lost four members in one year and six months. On the 18th of February, 1884, one died, three years of age, of cerebral effusion. On August 7th, the same year, one died of meningitis at the age of eleven years. On September 1st, 1885, one died, aged thirty-seven, from consumption. She was the mother; and on November 1st, 1885, the same year, two months later, a child three years and four months old died of meningitis. In that instance the case of consumption occupied the middle position, and cases of brain disease the others. Tuberculosis was not diagnosticated, although the woman must have been tubercular all the time. I have seen members of the family since; and they assured me the mother had tuberculosis, lasting about four years.

Here is a case, August 13th, 1882, where a child two years of age died of convulsions. May 1st, 1885, an infant two months old died of exhaustion. September 28th, 1885, a child four years old died of convulsions. April 30th, 1886, a child two years and two months old died of marasmus. No more about the family except last year I was called in to see the people, and found that they had three surviving children, all in good health—the father and mother in perfect health. I was asked to examine the mother's lungs, and I found signs of healed tubercular cavities. While these children were dying of various convulsive disorders, she was then coughing and spitting about the house. It seemed to me then that our statistics of tuberculosis should include almost all cases of brain disorder in children; that,

[1] Reproduced, by special permission of the author, from the eleventh report of the Maine State Board of Health, U.S.A.

[19] "Transactions" Mass. Assoc. of Boards of Health, iv., 3. 1894.

when as physicians we meet a case of brain disorder in a child, we should think of tuberculosis. And in the two histories that I have read the physical record shows us that, unless there is a person in the family who is actually tubercular (I mean by that, excreating tubercular pus), the children do not inherit it from their parents; and, if there is that condition of things, then children do inherit it.

During childhood, says Cornet, infection from inhalation shows itself as a primary tubercular development in the bronchial glands, while in later years it gives rise to primary tubercular deposits in the lungs themselves. The same author produces evidence that even among children, tuberculosis is much more frequently caused by inhalation of the infection than otherwise.

(*To be continued.*)

THE STAINES RESERVOIRS.*

By M. Mawson, A.M.I.C.E.

(*Continued from page* 112.)

The next work of importance is the pumping station, where the water which is to be put into store leaves the conduit, in order to be lifted into the reservoirs. The engine-house proper is 108ft. long by 55ft. wide, and will contain five triple-expansion Worthington pumping engines, each capable of lifting 16¼ million gallons daily to a height of 42ft. 6in., one of the five being held in reserve. The water is taken to the suction well of each engine through a concrete tunnel controlled by a penstock. The engines are surface condensing, the condensers forming part of the delivery from the main pumps. Each engine has its own air and feed pumps. The diameter of the cylinders are 11in., 18in. and 29in., and of the pumps, 35in.; the stroke being 30in. A 7in. centrifugal pump is fitted for draining any suction well if required, or for emptying the delivery mains of such water as cannot flow back into the conduit by gravitation.

An electric travelling crane capable of lifting ten tons is fitted so as to command the whole of the machinery, and the door at one end is so arranged that a railway wagon can be brought in from the siding to receive the load. Steam at 150 lb. pressure will be supplied by three pairs of Babcock and Willcox boilers, in a house 57ft. 6in. by 48ft. adjoining the engine-house, and furnished with convenient doors for unloading coal direct from the siding on to the firing floor. Each boiler contains 1265ft. of heating surface, and is fitted with a Babcox and Willcox superheater. Forced draught is provided by means of a steam-driven fan in an adjoining house, which contains also duplicate feed pumps and tanks, and an economiser of 240 pipes, with the usual arrangement of bye-pass flue.

At a short distance from the engine and boiler-houses, stands a smaller block of buildings comprising a workshop, with forge and the usual machine tools, and a house for the electrical machinery for lighting and power purposes. The elevations of these buildings are finished in gault bricks, with dark red terra-cotta dressings and light red brick arches. The chimney is round, 100ft. high and 5ft. in diameter, with a cast iron cap.

The delivery mains from the pumps are 4ft. in diameter, diminishing to 24in. at the valves and increasing to 4ft. 6in., and are of steel, each pair afterwards combining into a steel main 6ft. 4in. in diameter. There are two of these 6ft. 4in. mains, the engine in the centre of the row of five having a connection to both. The mains are of ⅜in. steel plate, with ½in. butt straps, and are laid side by side, being afterwards surrounded with concrete. Manholes are furnished at intervals of 100 yards for access to the interior.

Before entering the reservoirs the two 6ft. 4in. mains unite into one, 7ft. 10½in. diameter, afterwards again dividing into two branches of this size, in order that the whole of the water pumped may be passed into either or both of the reservoirs. The valves on all these mains are of considerably smaller diameter than the mains themselves, the latter being coned on either side of the valve on the "Venturi" principle. Thus the valves on the 4ft. pipes are 24in. diameter, and on the 6ft. 4in. and 7ft. 10½in. pipes 36in. diameter. The increase of friction due to this arrangement is hardly appreciable, while the saving in the first cost of valves is very considerable. The valves on the 7ft. 10½in. mains, and on the outlet mains from the reservoirs are contained in a well about half a mile from the pumping stations. The working floor will be at ground level, and will be enclosed by a brick building of the same general appearance as the smaller buildings at the pumping station.

The girders carrying the valve capstans will be covered by removable chequered floor plates, and a hand power traveller running along the whole length of the house will afford a convenient means of handling any portions of the valves which may require repairs.

Leading from the lower part of the well are two dry tunnels, approximately circular in section in the upper part, which are driven in the clay underlying the site of the reservoirs, until they reach the valve towers, with which they are united. These tunnels are built in concrete lined with brindled brick, the number of rings varying according to the position as regards the bank of the reservoir above, and the consequent pressure to be sustained. The tunnels are so graded that the drainage or the water from the scour valves on the mains will flow to a sump, over which is a well containing a centrifugal pump driven by an electric motor worked from the plant at the pumping station.

The valve towers, one in each reservoir, are circular concrete wells, 17ft. in diameter inside, rising from the tunnel end through the clay, gravel, and water in turn, till they reach the level of the top of the banks, or 5ft. above top water-line. The interior of the valve towers will be cut off from the tunnels by a stop or plug of brindled brickwork, surrounding the 7ft. 10½in. steel inlet main which is always open to the interior of the tower, and a 4ft. cast iron outlet main, which is carried up inside the tower to a point above top water level, and provided with valves for drawing off at different levels. The interior of the tower, and consequently of the pumping or inlet main, can be shut off from the reservoir by means of a large penstock of steel plates and girders, about 8ft. 6in. square lowered by gearing from the floor above, and closing an opening at the base of the tower, level with the bottom of the reservoir. The working floor of the tower will be covered by an ornamental brick building, and connected with the bank by a light lattice girder bridge.

The reservoirs themselves are two in number, separated by a cross bank. The top water area of the upper, or No. 1, is 178 acres, and its contents 1584 million gallons. The top water area of the lower, or No. 1a, is 246 acres, and its contents 1754 million gallons, giving a total area of 424 acres and a total capacity of 3338 million gallons.

The depth to which the puddle trench was sunk before reaching the clay into which it is keyed varied from 32ft. 6in. to 11ft. 3in. The thickness of puddle at the top is 6ft., and the sides follow a batter of 1 in 60 down to the ground level, thereafter narrowing to 4ft. at the junction with the clay bottom into which the puddle enters to a depth of 4ft. The whole of the clay used for puddle was excavated from the bottom of the reservoir, and ground in pug mills before use.

The banks are formed from selected ballast excavated

[20] "Die Verbreitung der Lungentuberkulose durch Contagion," page 17. 1884—Königsberg.

* Paper read before the Civil and Mechanical Engineers' Society, on Thursday, February 7th, 1901.

from the bottom of the reservoirs, the average depth required to form the banks being about 5ft. all over the area. The filling is carefully deposited in thin layers, well watered when required and rolled. The contractors' railroads are not allowed to cross over the puddle wall except where absolutely necessary, and then only on timber bearers, in order to avoid placing undue weight on particular points, and to do away with the possibility of unequal settlement. The banks when complete have a slope of 2 to 1 on the land side, and 3 to 1 on the water side, the centre bank being of course 3 to 1 on both sides. From the top down to a point equivalent to half the depth of water the inner faces of the banks are covered with slabs of concrete, 5in. thick laid *in situ* in sections 4ft. square, each alternate section being laid in the first instance, and the remainder filled in afterwards. A concrete wall or toe piece at the bottom edge prevents any tendency on the part of the slabs to slide down the slope. A flat benching 3ft. wide is formed outside the toe, and the remainder of the bank is faced with selected gravel, 9in. in thickness.

The top of the bank is 14ft. wide, and forms a roadway, and the outside slope on the land side is soiled and sown with grass seed in the usual manner, flights of steps being fixed at intervals for convenience of access. At three points on the bank a cart road is laid out on the face of the outer slope rising to the top of the bank at a gradient of 1 in 10, while the road on the top of the centre bank takes the place of a public footpath which formerly crossed the site.

The water from the reservoir, having been drawn off at the desired level, through the valves in the tower, passes down the 48in. cast iron outlet main already mentioned, through the valve well, and issues from a bell-mouth into a circular concrete basin forming the head of a conduit of smaller sectional area than that from the intake to the pumping station, with an invert 8ft. 3in. wide, and with a versed sine of 9in., the height and thickness of the walls remaining as before. This smaller conduit, which is capable of carrying 90 million gallons daily, returns to a point near the pumping station and close to the Billet Bridge under the London-road. Here it joins the conduit from the intake, which continues in the smaller section to Hampton, a distance of about six miles, passing under several public roads *en route*, either by bridges of the ordinary type or by syphons of concrete and brick. Of the latter a typical instance is the syphon at Shortwood Common under the London and South-Western Railway. The dimensions of the concrete tube are 8ft. 7¼in. wide at the springing of the roof arch, 6ft. 9½in. wide at the invert, the latter having a versed sine of 5¼in., and the roof having a rise of 2ft. 3in., the total height being 7ft. 8¼in. The arched roof is entirely of brickwork in three rings.

At the pumping station, on the down-stream side of the inlet to the pump wells, is a Stoney's patent sluice, 11ft. wide, by means of which the relative quantities of water passing to the pumps or flowing directly down the conduit may be regulated to a nicety.

The measurement and recording of the water pumped into the reservoirs and of that passing out will be effected by means of "Venturi" meters placed in the 7ft. 10½in. steel pipes at the point where the 36in. valves occur in the valve well, and in the 48in. cast iron mains in a special chamber built under ground to receive them.

The total quantity of water flowing down the conduit will be measured, in the case of the large conduit at the river Colne syphon, and in the small conduit at Shortwood Common syphon, by means of the relative opening of a balanced flap or door of sheet brass, built up on a light skeleton frame of cast iron. When no water is passing the door entirely closes the tunnel, and its movement is transmitted by gearing to the recording apparatus in a house above.

All these indications, as well as those of three distributing gauges at Hampton, and of water-level recorders at the intake and reservoirs, will be electrically transmitted to the pumping station, so that the state of affairs at any of these places can be ascertained by the superintendent without loss of time.

Along the route there are many watercourses of various sizes, but all of them at such a level that they have to be taken under the conduit in syphons. In most cases these syphons consist of a circular concrete wall at either side, connected by a concrete tunnel or a cast iron pipe, according to the amount of water to be passed. The wells are in all cases placed sufficiently far apart laterally to allow of future conduits being constructed alongside the first, without again disturbing the stream syphon.

At the greater number of stream crossings a 24in. cast iron scour pipe is provided, controlled by a valve, in order that the conduit may be flushed at intervals, and at as nearly as possible every mile an overflow weir is constructed in the side wall, provided with a swing shutter to prevent flood water in the stream flowing back into the conduit. At the bridge under the road from Sunbury to Hanworth, the East London Company's 36in. main to Finsbury Park was raised and taken over the conduit as a 36in. steel pipe, without any outside support. A few yards beyond this bridge, immediately to the north of Kempton Park, the New River Company will take their proportion of the water from the conduit into the works which they are now constructing, and from whence it will be pumped to the north of London.

After passing the Thames valley branch of the London and South-Western Railway, under a plate girder bridge, the distributing or balancing reservoir is reached, and the open conduit comes to an end. This reservoir is of comparatively small size, holding about 13 million gallons, with a depth of water of 7ft. At the western corner is an overflow weir 30ft. long, with a series of concrete steps leading to the Portlane Brook, the bed of which has been widened and prepared for the extra quantity of water which may at times pass down it. A 36in. scour pipe from the eastern end of the reservoir is taken into the same stream. From this reservoir will be taken the water apportioned to the Grand Junction and West Middlesex Companies. This water, as also that passed to the New River Company, will be regulated by a floating circular weir adjusted to allow no more than a certain depth to fall over into the interior of a telescopic pipe, and so to an open chamber separated from the water in the reservoir. In the event of the company concerned not taking all or any of the water, an automatic float recorder will show when the water in the rear chamber rose, and the gauge became drowned or ceased altogether to act.

The water will be carried to the existing works of the companies in 48in. mains of cast iron, the socket of each pipe having a steel hoop 1½in. by ½in. shrunk on.

The entire works, including a strip of land varying from 70ft. to 100ft. in width along the conduit, are enclosed by wrought iron unclimbable fencing, the total length required being nearly twenty miles. It may be of interest to note that the area of the reservoirs is about three-quarters of that of the city of London.

The author, in conclusion, desires to thank the joint engineers for their kind permission to use the material from which the foregoing figures have been compiled.

The death-roll from small-pox in Glasgow reached 120 on Monday; 387 patients were in the hospital.

A Local Government Board inquiry has been held at North Shields by Mr. H. Percy Boulnois, M. Inst. C.E., concerning an application by the Tynemouth Town Council for sanction to borrow sums amounting to £4539 for street improvement purposes.

THE SANITARY INSTITUTE.

THE STATE OF LONDON STREETS.

A SESSIONAL meeting of the members of the Sanitary Institute was held on Wednesday, 13th inst., at the Parkes Museum, Margaret-street, W. Sir Alexander Binnie, engineer to the London County Council, presided, and there was a large and representative attendance of London bodies of engineers and surveyors.

Mr. T. Blashill, F.R.I.B.A., late superintending architect to the London County Council, read a paper on the "State of the London Streets." He observed that the new metropolitan municipalities were recognising their enlarged powers and their heavier responsibilities, and he expressed the hope that the state of the London streets would early claim their attention. He asked them to agree with him that the streets are dirty and ought to be cleansed, because he could see the dirt and knew that the means of cleansing were at hand. He would not say that the streets of London were the dirtiest of any to be found in the cities of Europe, but amongst the great continental towns, whether capitals or not, there is nothing similar to them. In all such towns the streets, however they may be paved, are kept clean, chiefly by manual labour and the use of water, which in the summer at least is employed not only for washing away the slush or to keep down the dust, but for the pleasure and comfort of the people in the streets. Street dirt consisted of the wear and tear of macadamised roads, less from granite and wood pavements, least from asphalt. Then there was the sand used to prevent slipperiness. All these materials were comparatively of small account when contrasted with the great bulk of the horse droppings, worked up by wheels into slush in wet weather and ground into dust in dry. It trading streets there was a serious addition of animal and vegetable refuse, which would not exist if the law were properly enforced and special arrangements made for its collection. The Local Authority should pay more attention to the nuisance arising from dogs. Clothes were fouled by the street dirt, which was carried into houses in several ways. The effect of street dust on food in the houses would be an interesting inquiry. It was the poor who suffered most from dirty streets, which for thousands of children were their only playground. If the streets were clean the influence on the habits of a considerable proportion of the population would be great. Mr. Blashill then gave his experiences of street cleaning in Paris, Vienna, Berlin, Prague, Brussels, Buda Pesth, and Dutch towns, the position in these places being superior to that of London. He believed that street receptacles of one kind or another was the only satisfactory principle for coping with the dirt of the streets. Droppings should be collected fresh, and would then form valuable manure, and the manufacture of much dust would be prevented. The work of a scavenger should no longer be regarded as of a low class, or even unskilled; it should be well paid, and made attractive to respectable able-bodied men. The horse-broom should be used with discretion, and kept in good order; these brooms might do the heaviest work, but they had not the finish of hand labour. In concluding, Mr. Blashill said that it was his unhesitating opinion that the dirt in our streets has increased, is increasing, and ought to be diminished; and pointed out that, while large sums of public money were spent on education, comparatively small sums were spent on cleansing, watering, and lighting. His remarks were, of course, not intended to be anything more than an opening of the interesting discussion which he trusted they would have that evening.

Major ISAACS (Holborn), as one who had charge of an important London district for forty-five years, opined that the great factor which had produced the excellent results in Paris and other continental cities mentioned by Mr. Blashill was water. This was the element they wanted, but it was an expensive item in London administration. Then, too, if they used water in London as they did on the Continent, they would be subject to heavy penalties from the County Council for injuring the sewers. His contention was the metropolitan sewers were the proper receptacles for one-half the refuse of London, and given water and the use of the sewers, the problem would be solved.

Mr. EMERY (Marylebone Vestry) contended that the Local Authorities could not keep the streets clean until the filthy habits of the people had been reformed. He thought the police ought to be more strict in prosecuting persons who threw refuse from their houses into the streets.

Mr. W. NISBET BLAIR (St. Pancras) pointed out that the conditions of London and of continental cities were entirely different from each other. Not only were the climate and traffic different, but the police were much stricter, and householders were punished for throwing refuse about, and fined if their footway was not properly cleaned at certain intervals. Londoners would not submit to the strict continental regulations. Considering the small sums spent on street cleansing in London, he thought the Authorities were entitled to some credit for doing it as well as they did. With regard to increasing the amount of water used, they should not forget that all the water flowing into the sewers had to be pumped up again by the County Council.

Mr. WADDINGTON (Marylebone) spoke of the difficulties—the practical difficulties—of dealing with snowfalls. He explained how absurd were the newspaper criticisms on this subject, for it was financially impossible to keep an organised body of men ready for the work at a moment's notice. He had sixty miles of streets under his control, and to deal with this as the critics desired meant some 1400 or 1500 additional hands would be wanted. On the last occasion he could only get 300, and these were the dregs of the casual labour available for this work, because his Authority only paid 5d. per hour for such work, while the neighbouring Authorities paid 6d. per hour. If he had allowed him in Marylebone another ½d. in the £ per annum he could make a vast improvement in the general condition of the streets.

Mr. W. WEAVER (Kensington) said he thought the bad condition of London streets was much exaggerated. During the last forty years the state of things had immensely improved. Then peoplo would have mud up to their ankles every wet day and think nothing of it; now if a little mud was left anywhere complaints would be sent in by the score. Of course they must keep up to the modern standard as far as possible, but he thought the grumbling had come in with untanned leather boots and patent leather shoes. Horse droppings were the greatest nuisance; he got four tons a day per mile off the Kensington-road. He was now devising a street orderly to go under the kerbstones. He had once been complimented in a cycling journal as being the only surveyor in London who knew how to sand a road, and this was attributed to his being a cyclist. Now this showed how accurate newspapers were, for he used the cheapest sand he could get—it was dug up in his own parish—and he had never been across a bicycle in his life. He referred to the difficulty of organising scavenging labour, and said that a great part of the evils of which complaint was made was the constant opening of streets by public or private companies. For instance, in 1900 in 86 miles of road in Kensington 3928 trenches were opened; in addition trenches for electric lighting mains were opened to the extent of 7½ miles, and the telephone company to the extent of nine miles, or in all 16½ miles,

about one-fifth of the entire mileage; the cost of surface reinstating was £4625. The Post-office was now going all over it again in about nine miles of road with their telephone system. The nuisance and dirt arising from this source was incalculable.

Mr. W. Hunting, Mr. Gladwell, Dr. Smith, and others having spoken,

The Chairman pointed out that London laboured under a physical disadvantage as compared with many cities. London was built on a clay subsoil, and the least breaking of the surface caused masses of clayey mud. The sewers were not constructed to receive the street sweepings; in the first place, they were not large enough, and all the water that went into them had to be pumped up again at great cost. Any addition to their work in this respect meant a large outlay. Apart from that, water-borne sewage was valueless, and they ought not to sweep valuable manure into the sewers. As an illustration of the result of street washing, in Regent-street the deposit in the sewers since the watering had been adopted had risen from 9in. to 18in., and then to 2ft. 6in.; all this had to be removed by labour, because the fall was not sufficient to carry it off. Subways were regarded as the cure for the drawback of street opening, but only in new streets was this practicable, because the public companies having laid their pipes would not be forced by Parliament to do all their work over again, and the cost to the ratepayers of constructing these subways would be enormous.

A hearty vote of thanks to Mr. T. Blashill for his paper, and to Sir Alexander Binnie for presiding, closed an interesting and useful discussion.

Sanitary Inspectors' Associations.

NATIONAL UNION.

At a meeting of the North-Western Centre of the National Union of Sanitary Inspectors held at Ashton Hall, Liverpool, on Saturday, February 9th, Mr. Jas. Mort, chairman of the Centre, presided, and there was a good number present, including Dr. Daley, Bootle; W. Bland, chairman of the Union; J. T. Quinton, hon. district secretary; also Messrs. W. Stansfield, N. Coates, A. Gleave, A. J. Wilde, W. Urquhart, members of Council. Representatives were present from Liverpool, Manchester, Crewe, St. Helens, Lymm, Urmston, Birkdale, Formby, Bootle, Darwen, Litherland, &c.

When the business of the meeting had been disposed of, an important paper on "Tuberculous Meat and Milk" was read by Mr. J. S. Lloyd, M.R.C.V.S., Veterinary Inspector, Public Health Office, Town Hall, Manchester.

Mr. Lloyd introduced his paper by referring to the discovery of the tubercule bacillus by Koch, and the change of opinion regarding the nature of the disease which followed that discovery. Whereas it was formerly almost universally considered hereditary, now it has come to be known as a purely contagious disease, contracted by the absorption into the system of the bacillus tuberculosis derived from another individual affected with the disease.

After stating that the two chief methods of conveying the disease are by the inhalation and ingestion of tuberculous matter, the writer proceeds to point out the dangers incurred by the consumers of tuberculous meat and milk, as proved by numerous experiments in which different animals had acquired the disease as the result of being fed with food containing tuberculous matter, the latter in some instances being derived from a human origin and in others from animals. Although the disease had not been conveyed to man from animals by direct experiments, the writer quoted instances where such had been the case by accidental inoculation. The remarks and conclusions of the former Royal Commissions on Tuberculosis, contained in the report of 1895, concerning the danger to consumers of meat and milk derived from tuberculous animals, were next put forward, stress being laid upon the belief of the Royal Commissioners that persons consuming tuberculous matter incurred some risk of acquiring tuberculous disease, and that they regarded the disease in man and animals as practically identical, and transmissible from man to animals and from animals to man.

The writer next points out that tuberculous milk is considered much more dangerous than is the flesh of tuberculous cattle, and that the milk from cows having tuberculosis of the udder, in which tubercle bacilli could be found by microscopic examination, was excessively virulent, and without doubt a great source of danger to anyone who consumed it, as has been shown by numerous experimenters, Martin, Woodhead, Bang, Delepine, McFadyean, &c., who fed calves, guineapigs, pigs, and other animals upon it with almost certain infection in the test animals, and that the same thing occurs in human beings, particularly children, may be inferred from the prevalence of tuberculous disease of the alimentary tract, as shown abundantly by post-mortem examination and by the large percentage of deaths from tuberculous disease of the intestines among children. After bringing before his hearers the conclusions and recommendations of the last Royal Commission on Tuberculosis for controlling the danger arising from the consumption of tuberculous meat and milk, Mr. Lloyd points out that so far only very small steps have been taken by the Government towards carrying out their recommendations. Regarding the inspection of tuberculous carcases, the only thing the Government had done was to send out the instructions to meat inspectors, and in regard to milk from tuberculous udders, was to so amend the dairies, cowsheds, and milkshops orders, as to include in the word disease in Article 15, such disease of the udder as shall be certified by a veterinary surgeon to be tubercular, although certain powers had been given to several large towns under what are termed the "Milk Clauses." After explaining these, and how they are worked at Manchester, Mr. Lloyd drew attention to the great drawback that when cows having tuberculous udders are discovered, often after considerable expense and trouble, the clauses give no power to compel their slaughter, and so prevent such animals being sold from the farms where discovered to be used as dairy cows elsewhere.

After quoting figures from the agricultural returns regarding the prevalence of tuberculosis amongst bovines, and from the statistics of the Manchester Public Health Office (contained in the annual report of the Medical Officer of Health for 1899), regarding the percentage of tuberculous udders among dairy cows, the writer states that in his opinion steps should be taken to diminish these, both as a safeguard to the public health and in the interests of farmers and butchers. Whilst admitting that this meant considerable expenditure of public money, he states his opinion that to weed out the "wasters" and cows having tuberculous udders, with a fair compensation to butchers for the carcases of well fed beasts condemned in the public interests, would not cost so much as has been spent by the Government in its endeavours to stamp out swine fever, a disease which is not transmissible to human beings, and is little or no menace to public health.

Mr. Lloyd next gave details of a scheme for dealing with tuberculosis in cattle, which he had drawn up after considering somewhat similar proposals put forward by Delepine, Hunting, Laithwood, Wolstenholme, and others, and which, in part, includes the recommendations of the last Royal Commission on Tuberculosis. Put shortly, the scheme includes scheduling tuberculosis as a contagious disease, compulsory notification of "wasters" and cows having tuberculous udders, to be

followed by slaughter without compensation, powers to seize such animals in transit or in market, with penalties for being in possession or offering for sale, gratuitous testing of cattle, breeding only from cows and heifers which have passed the tuberculin test, erection and compulsory use of public slaughter-houses, uniform inspection of carcases by properly qualified meat inspectors.

A short account of the pasteurisation of milk and its adoption by Municipal Authorities and dairies completed the paper.

Discussion followed, in which the CHAIRMAN, Messrs. W. BLAND, W. STANSFIELD, H. HILTON, W. DALEY, and the SECRETARY took part. A vote of thanks was passed to Mr. Lloyd, who replied.

PUBLIC HEALTH IN IRELAND.

PROPOSED INSTITUTE OF PREVENTIVE MEDICINE.

AT the annual meeting of the Dublin branch of the British Medical Association, Sir George Duffey, M.D., the newly-elected president, in the course of his presidential address, referred to the proposal made by Sir Christopher Nixon to establish in Dublin an institute similar to that of the Jenner Institute of Preventive Medicine of London, which Lord Iveagh endowed with the splendid gift of a quarter of a million sterling It was to the study of bacteriolgy in relation to medicine, pathology, and to hygiene that they should look for more light in the treatment of disease and in their efforts for its prevention. In Dublin, and in Ireland generally, opportunities for such study were extremely restricted. They had not at present any properly-equipped recognised laboratories available for the application of bacteriology for public health purposes, to the diagnosis or to the prevention of communicable diseases. In Dublin, if a dispensary Medical Officer, or any other practitioner, desired in a doubtful or suspected case of infectious disease to have definite knowledge of the real nature of the case from a bacteriological examination, he should either put himself under an obligation to a member of the staff of some of the medical schools, or else pay a fee to a specialist, for an examination and report. In some of the large cities in England and in Scotland, particularly in London, Liverpool, and Edinburgh, the Municipal Authorities either support a bacteriological laboratory or subsidise one. In Germany, in France, and, I believe, in Italy, bacteriological laboratories are assisted by the Governments of these nations; and State bacteriological institutes have been recently established in various parts of Russia, including one at Merv, in Central Asia. In Belfast the Municpal Authorities have an arrangement with Dr. James Lorain Smith, the able lecturer on pathology in the Queen's College, to make bacteriological examinations in suspected cases of typhoid fever and of diphtheria, for each of which examinations he is paid a fee by the Corporation. It also grants an annual sum to the Council of the College for expenses—the examinations being conducted in the college laboratory. Special arrangements are made for larger investigations; and at present an important investigation is being made there on the value of bacteria beds for the treatment of sewage. Why should not some similar arrangement be made for Dublin? The results that have been shown to follow the investigation in such laboratories have been most valuable, and in many cases have undoubtedly prevented epidemics from spreading. The Irish Government has indeed to some extent recognised the importance of the information a competent bacteriologist can give by the appointment of Professor E. M'Weeney as bacteriologist to the Local Government Board for Ireland. But his official duties as such are limited in their scope, and he has to conduct his investigations in a small private laboratory, which he himself, I believe, would be the first to acknowledge is inadequate, both in size and in its equipment, for his work. It would seem most reasonable, therefore, that as neither the Corporation of Dublin, being the Sanitary Authority for the city, nor the Urban or Rural District County Councils of the County of Dublin, have as yet provided any means of giving any bacteriological assistance to their respective Medical Officers of Health in the diagnosis and prevention of infectious and epidemic diseases, that these bodies should, with the aid of Government, take action for the establishment and maintenance of a conjoint bacteriological laboratory, under the control of a highly qualified bacteriologist. In such a laboratory arrangements might also well be made for technical instruction in bacteriology for post-graduate classes, and for making original research. In the endeavour to arouse renewed attention to the importance of establishing such a laboratory in Dublin, I am entirely in accord with Sir Christopher Nixon's original proposal of forming one on the lines of the Jenner Institute of London.

National Health Society.

OFFICIAL TRANSACTIONS.

LADY SANITARY INSPECTORS.—We are very pleased to be able to record the success of two of our late students in the recent appointment of Lady Sanitary Inspectors in the Borough of Southwark. Both Miss Florence Nicolas and Miss Mona Richardson were trained for the examination of the Sanitary Inspectors' Examination Board by the National Health Society, and, in addition to the certificate of the Board, they hold the diploma of the National Health Society. It is most satisfactory to find that out of a large number of applicants for these two appointments the preference was given in both cases to ladies trained under the National Health Society. It is a further proof of the estimation in which the Society's training is regarded. Another of our students has been successful in obtaining an appointment as Sanitary Inspector in Bradford. Miss C. Florence Stephens attended the Society's training lectures at the same time as Miss Richardson and Miss Nicolas, and is also a diplomée of the National Health Society.

LECTURES TO THE MOTHERS' UNION.—One of the Society's lady lecturers has lately been giving some "talks" on Health to members of the Mothers' Union, at the Chapter House, St. Paul's. These lectures have been largely attended, and the audience has shown much appreciation of the instruction given.

LECTURES AT 53, BERNERS-STREET.—The fifth lecture of Dr. Cantlie's course on First Aid will be held at 53, Berners-street, on Monday, February 25th, at 3 p.m., when the subject of "First Aid for General Accidents, such as Foreign Bodies in the Eye, Ear, &c., Drowning, and Burning," will be dealt with. Sister Katherine will give the last lecture of her course on "Sick Nursing" on Thursday, February 28th, at 3.30 p.m.

ASSOCIATION OF NATIONAL HEALTH WORKERS.—The monthly "At Home" for members of the Association of National Health Workers will be held at 53, Berners-street, on Saturday next, February 23rd, at 3 p.m.

THE Burnham-on-Crouch Urban District Council and the Maldon Rural District Council propose to combine for the provision of an infectious diseases hospital.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

I HAVE been reading an admirable article on "The Bacterial Treatment of London Crude Sewage at Barking and Crossness," by Dr. Houston, F.R.S.E., which has been reprinted from the *Edinburgh Medical Journal*—wherein it appears this month—and published by Young J. Pentland, Edinburgh. Dr. Houston, it will be remembered, was appointed by the London County Council to investigate, from the bacteriological point of view, the experiments which have been in progress at Barking and Crossness on the bacterial treatment of sewage, and the reports which he has published in conjunction with Dr. Clowes, the chemist to the Council, form the highest and most valuable treatise on the biological qualities of effluents from bacterial beds extant, for prior to their publication there were practically no records on the subject.

I OBSERVE that Dr. Houston very properly and wisely observes that it must not be assumed that he is necessarily convinced that the bacterial process used during the course of the inquiry is the best one available, for it may be remembered I adverted in "Cross-table Chat" of the 17th January to the absence of originality and variety in the method of treatment of sewage in the experiments. To this extent it would appear that Dr. Houston dissociates himself from the responsibility as to the construction and working of the beds which was followed at Barking. But good as the results unquestionably are, he says he does not believe that they have reached the highest point possible in the bacterial treatment of sewage—a statement which, coming as it does from Dr. Houston, is very reassuring.

THE bacteriological experiments, it is to be noted, showed that the effluents, though excellent from a chemical and practical point of view, contain a large number of pathogenic microbes, and that, although fit to discharge into streams not used for domestic water supply, such effluents would not be safe in streams used for that purpose. It is, however, so rare that the outfall from sewage works discharges into a potable water supply that possibly this condition is not generally of prime importance, but it would be of especial interest to learn to what extent effluents from sewage treated on land, *i.e.*, by broad irrigation, vary in this respect from contact beds, and whether pathogenic microbes are removed by land treatment, for the objection seems to be more pedantic than practical.

I SEE that the objection may be met, if required, for Mr. R. F. Wood Smith, a bacteriologist and chemist, has patented an invention for sterilising and aërating effluents which have undergone bacterial treatment by the Dibdin's or Sutton process, or the Exeter septic tank process, by causing ozonised oxygen or ozonised air—that is air impregnated with ozone, as the case may be—in suitable proportions to be forced into the effluent, the requisites being an ozone-producing apparatus and a pump and a system of pipes by which the gas is conveyed into the effluent channel. The Royal Commission on Sewage Disposal, I am informed, are desirous of testing the system, and view it with some interest.

BUT I am not sure that this idea of sterilising effluents will not be prejudicial rather than beneficial, for it has been advocated all along by bacteriologists themselves that one of the valuable features of the bacterial system was the presence of the bacteria in effluents and that by their agency such effluents were further purified. The action of chemicals, it has been discovered, was to destroy or paralyse the micro-organisms and to retard decomposition of sewage, and this, it has been found, was an error. The bacterial system proceeded on directly opposite lines, and the micro-organisms were found to be beneficent creatures, which if properly harnessed would work out the purification of sewage by themselves. I greatly doubt whether this straining after the destruction of a few possibly pathogenic microbes by sterilisation will not result in the complete destruction of the non-pathogenic microbes, and harm, not good, will result. As I have already remarked there appears to be a lack of practicability in the suggestion generally.

THE Board of Trade have notified that the time has arrived when the maximum price of 8d. per unit, which has been allowed by them to be fixed in granting Provisional Orders, should be reduced to 6d. Since the date when the former maximum price was fixed the improvements in the manufacture and distribution of electricity have been so great, thereby lessening the cost of production—and undertakers, as a rule, charge much less than 8d.—that the Board propose, both with regard to all applications now before them and in future, to restrict the maximum price per unit to 6d.

IN carrying out new sewerage schemes in districts hitherto improperly sewered it is often a source of doubt with Local Authorities as to whether they are enabled to require the owners of private drains to connect their premises to the new sewers. Moreover, these old drains are generally constructed of improper materials, and are rarely water-tight, and as such should be entirely relaid. Some Local Authorities provide for the cost of connecting existing house drains to the sewers, and obtain a loan for the purpose. Others, on the contrary, succeed in getting the owners to do the work at their own cost by a judicious exercise of the provisions of Section 23 of the Act of 1875, which empowers a Local Authority, where a house is without a drain "sufficient for effectual drainage" to make such a drain as they may direct and connect to the sewer.

IN one instance which has come under my observation, where a Local Authority proceeded under this section and a ratepayer appealed to the Local Government Board against the Local Authority's interpretation of the words "sufficient for effectual drainage," the Board replied, "It appears to the Board that unless a drain is water-tight it cannot be considered sufficient for effectual drainage." Moreover, they added that as regards the question as to the material of which the drain should be constructed, this was one which they had no authority to decide, but they were advised that an engineer or architect of standing and reputation would not consider a drain "sufficient for effectual house drainage unless it were constructed of glazed earthenware pipes or of some other material; for instance, iron pipes equally strong and water-tight." I doubt not the information may be of some use to my readers.

SENEX.

THE REGISTRATION OF PLUMBERS.

FROM all parts of the United Kingdom questions have been asked us recently concerning registration that we think it desirable to again call our readers' attention to the fact that, at the recent Conference at Birmingham, it was decided to recognise as eligibe for registration in the grade of operative plumbers all operative plumbers who have already passed the requisite examination in workmanship, or who produce proof satisfactory to the Registration Committee of their district that they are earning the standard rate of wages in the district in which they may be working—provided such operative plumbers apply for registration not later than February 28th, 1901.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

FEBRUARY 21, 1901.

THE KING'S SPEECH.

FROM the standpoint of the public health worker, the outstanding features of the Royal Address with which Parliament was opened last week were the promise of two important measures affecting the public health, and the omission of all reference to another most important subject in regard to which keen expectation had been aroused. The promises related to Bills for the amendment and consolidation of the Factory and Workshops Acts, and a Bill for the amendment of the Public Health Acts, particularly in regard to water supply. By the time this issue appears we shall have more information as to the scope and character of these projected measures, but at the time of writing they remain subjects for speculation. Curiosity will be especially keen with regard to the Bill of which Mr. Long has given notice, as though its main purpose is apparently to deal with questions of water supply, it is also to include "other matters" relating to the public health. What these may be, and in what manner it is proposed to deal with the subject of water supply, are questions in regard to which we cannot in the meantime hazard a forecast. The same remark may also be made in relation to the amending Bill of which Mr. Ritchie has given notice on the subject of the Factory Acts. But the purpose of Mr. Ritchie's second Bill is clear and free from ambiguity. It is to consolidate the complex system of the Factory and Workshops Acts. This much-needed measure has long been demanded, and it will be hailed with acclamation by all those engaged in the administration of the Factory Laws, for in the present maze one never knows where to turn, and cannot be sure of solid standing ground. It is to be noted, however, that these measures do not stand in the front rank of proposed legislation. They are embraced in the list of Bills which have been prepared, and, "if the time at disposal shall prove to be adequate," will be submitted. The promise of legislation in the directions indicated is, therefore, only provisional, but we trust that the early introduction of the Bills in which we are interested is an augury that they will be dealt with in earnest by the Government, and pressed to a successful issue.

The important omission to which we have referred is that of the housing question. No reference is made to the subject in the King's Speech, though the manner in which the subject has recently been alluded to by Lord Salisbury and other members of the Ministry undoubtedly awakened a belief in the country that it was to have some place in the legislative programme. This hope has been disappointed, to our great regret. The question will, however, be raised in the debate upon the Address, for Mr. Macnamara has already put down an amendment representing that the growing evil of the lack of proper housing accommodation for the working classes is one of the most pressing necessities of domestic policy demanding the attention of Parliament. The probability is that though the Government are firmly convinced of the gravity of the evil, they are not yet clear as to the course which legislation should take, or the nature of the remedies to be proposed. And for this attitude perhaps some apology may be found in the proceedings of such a Conference as the one at Manchester the other day, which was chiefly noteworthy for the variety of the suggestions put forward by the different speakers. It must be confessed that at none of the Housing Conferences that have been held within the last year has there been formulated a clear and distinct line of policy, backed by unanimous support, that could be made the basis of new legislation. Probably the point as to which greatest unanimity obtains is that which was urged upon Mr. Long last week by the

deputation from the National Housing Council—the extension of the period for which loans might be granted, say, to 100 years, at least in regard to land, whereby municipalities might be enabled to reduce rents, and materially contribute to the better housing of the poor. But even on this point Mr. Long has his doubts, though we fail to perceive the force of his objections. A perusal of his reply to the deputation leaves us in the greatest uncertainty as to what his attitude on the question actually is. There can be no doubt of his sympathies with the object aimed at, but his suggestions of remedies for the present intolerable state of matters have the attribute of vagueness. The same thing cannot, it is true, be said of Mr. A. J. Balfour's important letter, written on the eve of the assembling of Parliament, to Mr. F. H. Stead, in which he deals with the improvement of the means of locomotion as a factor in the solution of the problem. It is definite and concrete throughout, particularly in his exposition of his idea of a system of radiating thoroughfares for "confine-rapid" traffic, such as autocars. The picture that he draws is undoubtedly a most attractive one, but it is difficult to understand how he would propose to apply his idea practically to the existing conditions of city life, especially as existing in London, with its irregular labyrinth of streets. He claims that if improved locomotion is the real key of the housing difficulty, his scheme would provide the cheapest, the easiest, the most flexible, and the most convenient form of providing it, and its advantages he sketches with considerable detail. But he does not explain how his system of radiating causeways is to be laid down, without upsetting a whole city's arrangements, nor at what cost. We should welcome, however, a fuller exposition of the subject.

An Exemplary Sentence.

The action of Mr. Hopkins at the Lambeth Police-court last week should have a good effect upon those who think they can evict people without regard to their condition or the injury done to them. The action was brought at the instance of the Camberwell Borough Council against two men "for removing a quantity of bedding and furniture which had been exposed to infection without having afterwards been disinfected." A poor woman had the misfortune to have three of her children taken with scarlet fever, all of which were removed to the hospital. Unhappily, however, she had some dispute with the landlord over her occupancy of the rooms in which she lived, and the consequence was she was called upon to leave, and in the event of her not doing so a bailiff was instructed to take action. The Sanitary Inspector, however, was on the spot, and warned the bailiff of the danger he was running. But this individual "had instructions," and scarlet fever or no, he was sent to put the things out, and out they would go, and this, despite the promise of the Inspector that he would have them disinfected if left alone. But the bailiff thought he knew better than the Inspector or anyone else, and out the things went, with the result that ere evening came "children and adults were crowded round the infected bedding, which was placed at the side entrance of a tenement house." For this performance the magistrate inflicted a fine of £5, with an additional five guineas for expenses. With such a punishment we do not think he will repeat the offence.

A Wiltshire Village.

Dr. J. Tubb Thomas, the County Medical Officer for Wiltshire, is trying to do something to improve the sanitary conditions of the villages of his county, and if there are many like that of Ludgershall, the need for such work is indeed great. Last December this officer paid a visit to the village named, and his report, which has just been published, reveals a most deplorable state of affairs. For years the population of the place has been decreasing, but recently the army authorities have purchased land in the adjacent district, and people have been attracted to the district. The consequence is that rents (which before were fairly low) have been raised, but nothing has been done to make the houses habitable. What they are like may be gathered from the description given by the Medical Officer. He says:—"The majority of the cottages are thatched, hardly any have any rainwater spouting, and none any drains, the walls are damp, floors and ceilings and stairs very dilapidated and in many instances dangerous. Slops are supposed to be thrown upon the gardens, but in the majority of instances they appear to be thrown into shallow holes near the back door with other household refuse. The privy accommodation of the village can only be classed as scandalous, hardly a cottage with a brick or stone built privy, the majority being rough tumbledown wooden shanties, some without three sides and a door, and all with a roughly dug hole for a cesspit, the greater number of these holes imperfectly covered, and the seats in bad repair, and all smelling most offensively. I cannot say that during the whole day that I saw a single privy in a sanitary state."

A Polluted Water Supply.

This is bad enough, but the sources of water supply indicate an even greater danger to the inhabitants. It is derived from deep wells in the chalk, but little care seems to be taken to safeguard its purity. A large number of houses on the Andover-road derive their supply from a public draw-well on the roadside. This well, says Dr. Thomas, "is imperfectly protected at the top, and each person brings her own bucket, with the result that dirty buckets are lowered into the well, with consequent serious risk of pollution. Whilst standing at the well with Dr. Lawrence we saw two very dirty buckets being used; from one I scraped off the dirt with my finger to show the user how dirty the bucket was. This well should be more perfectly protected at the top and a pump fixed, and until this is done a bucket should be attached to the

rope, and all persons using the well thus obliged to pour the water from this bucket into their own vessels, instead of lowering their dirty buckets into the well. Some of the private wells in the village are equally liable to pollution. At one baker's I found a filthy pig-stye practically on top of the well. At another baker's there was a very large heap of night-soil, within 25ft. of the top of the well, besides several cesspits. At another there was a large manure heap containing several tons of manure within 25ft. of the well. All these wells are dried steined, and there is nothing to prevent surface water percolating into them, the subsoil being chalk and full of fissures." The advent of the military to the district has caused a large hotel to be erected at a cost of over £9000, with at least nine water-closets. Practically the whole of the site will be covered with buildings, and it is proposed to obtain the water supply from wells sunk upon the site, which is riddled with old dumb-well cesspools. The doctor was informed that two wells at present upon the site are polluted and unfit for use, and yet it is expected to obtain a pure supply from the limited site. The whole of the sewage of this large hotel, with its nine water-closets, is to be led into a cesspool upon the site; this cesspool will be within 3ft. 6in. of the walls of the house (the commercial room end), and it may be said that the sides of this cesspool will adjoin the foundations of the house. There are no sewers in the village, so there are no other means of dealing with the sewage other than with a cesspool, but it is extremely undesirable that the sewage of such a large hotel should be dealt with upon so contracted a site. Dr. Thomas concludes his report with several recommendations, which the local District Council has been invited to see carried out. It is to be hoped that body will do this. But the question is—May this village be taken as a sample of those surrounding the new great military encampment which is being formed in the district? If it does, no time must be lost in working a change, or else outbreaks of enteric will not be confined to the war-devastated veldt of South Africa.

The Cry for Better Houses.

No matter which way we turn, or in what paper we look, on every hand there are indications of the impression that the most important social problem of the day is that of "Housing." Liverpool men speak of it on every conceivable occasion. One Councillor opened a bazaar the other day and took occasion to bring forward a proposition to create a conglomerate Committee from the Watch, Health, Insanitary Properate, Parks and Gardens, and Water Committees of the City Council. The members of such a body, he thought, might, by the aid of experience gained on their respective Committees, formulate some practical solution of the difficulty. Middlesbro' and the Hartlepools, on the east coast, are also anxious to better the condition of their workers, and, in fact, there is hardly a municipal body in the country but what has been stirred up in the matter. On Saturday last Bristol had a special conference, at which over 200 delegates were present from all parts of the country. The conclusions arrived at urged that it was necessary (1) to extend the period for repayment of building loans under Part 3 of the Act of 1890 to the full statutory period of sixty years, instead of restricting it, as at present, to thirty or forty years; (2) to relax the Model Bye-law of the Local Government Board which prohibits the building of an attic third floor on the 9in. wall of a cottage; (3) and in favour of power being given to municipalities to obtain land at a price based on its assessable value. It was pointed out that these first two simple things could be done by a stroke of the pen, and would enable a third bedroom, so often needed, to be added to a cottage at a very small cost, thus reducing the proportionate rent of cottages by at least a shilling per week.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

NEW YEAR'S PRESIDENTIAL ADDRESS.

By J. B. Wilkinson, D.P.H., &c., M.O.H. County Borough of Oldham, and Consulting M.O.H. County of Huntingdonshire.

(*Continued from page* 143.)

Perhaps in the pollution of water supplies one system is not more detrimental than the other, when both methods are managed with equal care and provided that the sewage or refuse is not disposed of near to any water source. That the water-carriage system has disadvantages cannot well be denied, although its advantages considerably overbalance any that may be raised. Many of the apparent disadvantages are really due to improper fixing or erection in the first instance. Leakage from the pipes through imperfect joints cannot be correctly enumerated as a fault of the water-carriage system. Nor can the contamination of the water cistern, in consequence of a direct connection with the closet, or the constant breaking of the seal, and the consequent introduction of sewer gas into the dwellings through the omission of a ventilating pipe to obviate this. These and many other undesirable incidents which constantly occur in connection with the water-carriage system are not due to the system itself. The risk of blockage of the pipe leading from the closet may, perhaps, in rare cases, be due to the system, though I think the instances where a blockage occurs without some contributory neglect on the part of the users is an exceedingly rare occurrence.

It is well known that when a closet is used by those who are naturally careless, or by those unaccustomed to the use of one, blockages frequently occur.

It is a general idea among these persons that a drain is a receptacle for everything which will go into it, and as a closet has a larger opening leading into the drain than the ordinary inlet, it is therefore a much more convenient place in which to empty ashes, rags, and rubbish of all kinds. It is generally nearer than the ashpit, and much easier to dispose of the latter in this way than by burning them. There are, however, certain disadvantages which are really incidental to the water-carriage system; one of these is the risk of freezing. While I am of opinion that this disadvantage has been considerably exaggerated, there is no doubt a risk of the pipes or cisterns freezing in outside closets, and especially in exposed districts. To a considerable extent this may be obviated by having the pipes properly packed, and

the doors and windows made to fit properly, but still it does occur in severe weather, and this is a time when skilled assistance is most difficult to obtain.

A little trouble on the part of the householder by hand flushing would tide over the likelihood of any serious inconvenience until the frozen pipes had been attended to, but I much doubt if the average householder will give this requisite attention. In those houses where the closets are built close up to the wall of the house the liability to freeze may be almost entirely prevented by the pipes and cistern being placed inside the house, care being taken that the closet does not ventilate into the house also. The blockage of a water-closet in the winter during a frost is the least harmful time also for excreta to be maintained in the proximity of a dwelling, as bacterial life is at this time in an almost inactive stage, and cannot be compared with the retention of excreta in the warmer weather, when the conditions which promote the extension of certain infective diseases are most prevalent.

A second objection against the general adoption of the use of water-closets, which in many places constitutes a real difficulty, if not negativing them altogether, is the increased water supply which is necessary, and the necessity of having a head of water or water at a higher level than the closet. In small communities the usual absence of any pumping force for the supply of the cisterns would be a very serious obstacle to the general adoption of the water-closet, as only few houses would be able to carry out the necessary hand pumping. The necessity for a greatly increased supply of water is, however, in many places the greatest difficulty. The rapidly increasing populations of our large towns, and the increasing use of more water by individuals as their knowledge of its use advances, render Municipal Authorities exceedingly chary of introducing measures which will increase the use of the already none too plentiful supply of water; and in recent years an entirely new form of closet is gradually gaining favour, being a sort of half-way house between the conservancy system and the best of all methods, the clean-water closet. These slop-water, or waste-water closets, as they are called, do away with the retention near dwellings of refuse, and save the cost of its removal, and at the same time do not require any increase in the quantity of water used, or, at least, only a very small additional quantity.

(To be continued.)

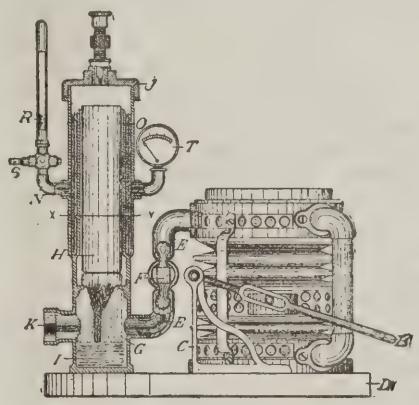
At a meeting of the Election Committee, held on the 13th inst., the following gentlemen were elected:—

Members: H. J. S. Abrams, London; W. N. Cosgrave, Straits Settlements; T. A. Croghan, Buxton; J. E. Scott, Newcastle-on-Tyne.

Associates: G. W. Bird, Ripley; A. E. W. Blissett, Clifton; W. T. Mansfield, London; J. J. Pratt, Hillingdon.

A NEW DRAIN TESTER.

Anything that is calculated to make the work of the Sanitary Inspector lighter, and at the same time more efficient, is worthy of more than passing notice. Drain-testing is one of the most important pieces of work these officers have to perform, hence the need for the best apparatus. There are several features in the drain tester just introduced by Mr. Richard Ravenor, of Newbury, Berks, which appear to be a distinct advance on many of the machines at present in use. Its compactness will be at once apparent from the subjoined illustration. It is designed for testing drains and soil-pipes by means of smoke and air pressure, and has for its object the arrangement and construction of an apparatus with which smoke rockets can be used effectively in drains of considerable length without danger of explosion of unconsumed gases emitted from the previous rocket. A further claim is that its ready adaptability is secured for testing with air and smoke separately or combined, at high or low-pressure as desired, viz., from ½ oz. to 10 lb., or more. Another valuable feature is its extreme portability, simplicity, and small size, which is gained without any sacrifice of capacity and usefulness. Time and expense are saved in testing long lengths of drains, as a number of rockets can be fired successively without disturbing the connection with the drain, and without fear of explosion. At the bottom of the smoke chamber G will be found a small receptacle I for containing water, which will catch and extinguish any sparks or incandescent material that may be emitted by the rocket during combustion. Fresh rockets may be inserted by simply removing the brass cap J at the top of the cylinder. To test with low-pressure, after stopping all ventilating



pipes, connect the hose to drain, work the bellows, and if the water in the annular channel O rises in the gauge R, close tap F, and if water remains in the gauge it proves the drain sound. If unsound, the user takes off the cap J, and inserts a smoke-rocket to discover the whereabouts of the leak. If high-pressure is desired, he simply turns off the tap S, and proceeds as before.

We understand that Mr. Ravenor has subjected his apparatus to several very severe tests, and that it has been able to fulfil all that has been required of it. Its compactability alone makes it worthy the attention of all who have use for such machines.

Public Works.

SEWERAGE.

Application is to be made for sanction to a loan of £2800 for the provision of two filter beds at the Longton sewage farm.

Tenders are to be invited by the Poole Town Council for machinery in connection with the sewage works in course of construction.

So successful have the two experimental beds of half an acre each proved that the Rivers Committee of the Manchester Corporation last week resolved to have ten others, of similar capacity, for treating the sewage of the city by the bacterial method.

The sewerage scheme for Senghenydd, Abertridwr, and Caerphilly has been constructed by Mr. T. Rossiter, builder, Caerphilly, at a cost of £13,000. The last pipe was laid last week. The work has been accomplished within twelve months, and the main extends from Senghenydd to Wainybarra Farm, a distance of about six miles.

THE revised estimate of Mr. Baldwin Latham, C.E., of the proposed sewerage works for Tarporley is £5170 instead of £4736. Application has been made for power to borrow £4500.

MESSRS. KAYE, PARRY, AND ROSS, Civil Engineers, of Dublin and Westminster, have been appointed Consulting Engineers for the Armagh Main Drainage Works, which are being carried out from the plans and specifications prepared by Mr. J. Finlay Peddie, C.E., of Belfast.

THE Local Government Board has written the Foleshill Guardians giving notice of an inquiry to be held respecting an application of the Coventry Corporation to borrow £32,962 for a sewerage scheme for the area added to the city. The Clerk, answering Mr. Gossage, said that Mr. Newey, the Surveyor, had seen the plan and he knew what sewers would be in Foleshill. It was only a short length, and the Council would be protected under the Public Health Act, so far as highways were concerned.

WHEN Chicago first proposed to construct a drainage canal by which the city sewage would be turned into the Illinois and Mississippi rivers, the chief opposition to the project was from those who thought the canal would lower the level of the great lakes, making the Mississippi a rival of the St. Lawrence as the outlet of the lake waters; but the people of Chicago went on with the construction of the canal, and spent 34,000,000 dols. upon it. When the canal was completed it did not have any appreciable effect upon the level of the lakes; but an outcry arose from the city of St. Louis that its water supply was being contaminated by Chicago. The United States Supreme Court has decided in favour of the city of St. Louis, and unless Chicago can prove that the flowing water is purified before it reaches St. Louis, the canal cannot be used for the purpose for which it was constructed.

THE Haywards Heath drainage inquiry ended on Tuesday in last week, the Haywards Heath Urban Council withdrawing its application for compulsory powers to acquire the site it proposed taking for sewage disposal at Lindfield. The agreement is that Mr. Sturdy, of Lindfield, will sell another site to the Council on agreed terms, and that neighbouring owners will contribute among themselves a sum of money to compensate Haywards Heath for the additional cost of having to go further afield with their sewage. A further agreement is to be made between Haywards Heath Urban Council and the Cuckfield Rural District Council to also take away the present sewage field at Lindfield, the Local Government Board to decide if there should be any difficulty as to terms between the two Authorities. The whole of the Haywards Heath and Lindfield sewage is to be taken eastward; but no mention has yet been made of the site.

THE new sewage works at Coventry, which were commenced in March, 1898, are now completed, with the exception of a few minor details, unimportant in themselves, and yet of moment to the general operation of the works. The scheme, which it will be seen has taken nearly three years to complete, has been carried out practically as designed, no extensions or additions having been made, and only a few slight modifications having taken place. The system of treating the sewage will be on the principle known as broad irrigation, and for this purpose the Corporation acquired nearly 500 acres of land in the Avon Valley, between Bagington and Ryton. This land has been laid out as a sewage farm; various pipes, carriers, and sewage distribution works have been constructed, so as to enable the sewage to be applied to any portion of the farm area. This is by far the most costly sewage scheme that has been adopted by the Coventry Corporation. The pumping station and plant will account for some £40,000; the cost of the works in connection with the rising mains and the laying out of the farm will amount to about £42,000; while, in addition to all this, there are certain works being carried out by the Corporation by administration, so that the total expenditure, wholly exclusive of the cost of the land, will probably be £100,000. The farm itself was purchased at a cost of £100 per acre; the scheme, therefore, when fully completed in every detail, will have entailed an expenditure of no less than £150,000. The City Council has decided that the whole of the sewage works shall be under the management of a separate Sewage Committee, which has been duly appointed.

IN answer to a communication from Captain Pasque, of the Royal Engineers' Office, Cardiff, the Clerk of the Porthcawl Council has been instructed to write that the Council is making application to the Local Government Board for the sanction to lease the land now used as irrigation ground by the War-office authorities for the purpose of erecting a rifle range, and also to borrow money to displace the sewage by a fall to the sea. A motion has been carried authorising the Clerk to draft such an application to the Local Government Board.

A LOCAL Government Board inquiry has been held at Doncaster by Mr. W. O. E. Meade-King, C.E., as to the compulsory purchase of land for sewerage and sewage disposal purposes for Askern, Bawtry, Bentley, Bentley-road, and Arksey. The schemes, which have been prepared by Messrs. D. Balfour and Son, of London and Newcastle-on-Tyne, comprise the main sewerage of the above places, all of which will gravitate to underground storage tanks, from which the sewage will be pumped to the site of disposal works there, to be treated in bacterial tanks, and afterwards on land. Various opponents to the scheme were represented by counsel, who objected chiefly on the ground of cost.

THE Doncaster Rural District Council and the Denaby Parish Council, having appealed against an order of the County Council of the West Riding of Yorkshire, granting urban powers for a portion of the parishes of Conisburgh, Denaby, and Cadeby, a Local Government Board inquiry was held by Mr. W. O. Meade-King, C.E. The appellants called numerous witnesses as to the present government of the parishes; and also Messrs. D. Balfour and Son, of London, as to the existing and proposed sewerage works; and Mr. Eaton, of London, as to the water supply. The defendants, the Parish Council, called no evidence, but had their case stated by counsel. The Inspector carefully viewed the district, and will report in due course to the Board.

A LOCAL Government Board inquiry was held at Waddesdon by Mr. F. H. Tulloch, M.I.C.E., last week; into a petition presented by the Aylesbury Rural District Council for power to put in force, with reference to certain lands required by them for purposes of sewage disposal for the township of Waddesdon, the Land Clauses Act, with respect to the purchase and taking of lands otherwise than by agreement. The land in question was about three acres of glebe adjoining the Quainton-road, of which the Rev. Dr. Yule, as rector, is the life owner. Mr. Guest Luckett, Engineer to the Council, was present, and explained the scheme to the Inspector. On the following day a similar inquiry was held at Haddenham by the same Inspector. Mr. G. Luckett on this occasion was also present as engineer of the scheme, and explained the plans. In both cases there was considerable opposition.

THE principal business at the meeting of the Burton-on-Trent Town Council last week was the consideration of the report of the Committee appointed to deal with the defective drainage of the sewage farm. The cost up to the present of putting the matter right had, it was stated, been about £1350. The Committee regretted that, owing to the lapse of time that had occurred, it was impossible to properly fix the blame for the systematic fraud that was evidently carried on by some of the gangs of men employed, with the cognisance of the foreman, who had been dismissed. A long discussion ensued, during which the Committee's report was severely criticised because of its paucity of detail, and eventually an amendment was accepted providing for the members to be supplied with a full and ample report of the negotiations which had taken place on the matter.

WATER.

THE Local Government Board has sanctioned the loan of £9026 for a water scheme for Bewdley.

AT the annual meeting of the Thirsk District Water Company, it was reported that the receipts for the year 1900 amounted to £1521, an increase of £154. The profits, after charging interest on the debentures, were £983. A dividend of 3 per cent. per annum is proposed, leaving £263 to be carried forward.

At the last monthly meeting of Wishaw Town Council it was reported that, granted favourable weather, the new waterworks (costing fully £100,000) would be so far finished that it would be possible to turn on the new water supply by the 1st of March.

Last week, at the West Gloucester Water Company's works at Frampton Cotterell, the formal opening of a new engine-house and pumping engine took place, in the presence of several directors, shareholders, and other gentlemen interested in the progress of the company.

The water supply for the district of Herrington, which has been very unsatisfactory of late, has been remedied, and active preparations are being made with the building of a large water reservoir on the top of West Herrington Hill for the purpose of containing the water which is being pumped from a spring at East Herrington, and which is to supply the entire colliery district named.

The Llanelly Borough Council has now decided to grant a water supply to Burry Port, the daily consumption not to exceed 300,000 gallons. The question of water supply for this place has been under consideration for a long time, several local schemes having been propounded. None of these were free from serious objections, however, and in the end it was decided to fall back upon a supply from Llanelly. The price charged will range between a minimum of 4d. and 6d. per 1000 gallons.

A water diviner has offered his services to the Sculcoates Rural District Council for the benefit of Preston. Last week, when the matter was discussed at the meeting, presided over by Mr. J. H. Fisher, it was suggested that the Local Government Board would not sanction any expenses of people with divining rods, however excellent the testimonials. Some members thought that pure water existed in the neighbourhood, but they doubted whether the quantity would be sufficient for the supply of the village, and the diviner's letter was left on the table.

The scheme of the Barrow Corporation for taking water from the river Duddon and Seathwaite Tarn, and for which a Bill is being promoted in Parliament, is meeting with considerable opposition. Millom District Council has decided to oppose the Bill, and the Hodbarrow Mining Company contemplate like action. Several farmers, who have sheep-dipping rights in the river, also propose to oppose unless the Barrow Corporation will guarantee them their present rights and privileges. The Corporation has come to terms with the Ulverston District Council, and is at present negotiating terms with the Dalton Urban District Council.

The question of supplying the villages of Dyffryn and Llwyngwril with a wholesome supply of water has engaged the attention of the District Council for a period of at least four years, and even now a start has not been made in either one case or the other. At Dyffryn two likely sources have been inspected, but not yet finally decided upon, the source near Llwyngwian being the favourite. At Llwyngwril matters are more advanced, although greater progress is desirable. An attempt is to be made to get this supply completed before the summer season, and, granting a favourable report from the inquiry to be shortly held, as well as the co-operation of landowners, this desirable state of things may be brought about.

At the Guildhall, Westminster, last week, before Mr. Perrin, M. Inst. C.E. (Official Water Examiner), Dr. Theodore Thomson, and Mr. E. A. S. Fawcett, a Local Government Board inquiry was opened with reference to a set of regulations for the prevention of the waste and misuse of water, which have been prepared by the eight metropolitan water companies and presented to the Local Government Board for approval. Mr. Cripps, K.C., made a lengthy statement on behalf of the water companies. He complained of misrepresentation with regard to their objects, and declared that it had been proved before Lord Llandaff's Commission that it was the imperative duty of the companies to prevent the awful waste of water which went on in the Metropolis, and which had caused in the past a serious inconvenience to those consumers who made use of the water in a proper manner. It had been shown to that Commission that there was a waste of five gallons of water per head as a rule, which in London amounted to 60,000,000 gallons a day. This had led to water famines, and it was a wastage which must be made good.

At the last quarterly meeting of Louth Town Council, the Highways Committee reported in favour of the purchase of the Louth Waterworks, and advised that a sum of £15,100 be offered for the undertaking. It was decided to discuss the question in committee of the whole Council.

The average daily supply of water delivered from the Thames to the Metropolis during the month of December last was 113,384,458 gallons; from the Lea, 44,204,673 gallons; from springs and wells, 40,471,192 gallons; from ponds at Hampstead and Highgate, 110,027 gallons. The last is used for non-domestic purposes only. The daily total was, therefore, 198,170,350 gallons for a population estimated at 6,165,490, representing a daily consumption per head of 32·14 gallons for all purposes.

At Ashill, Norfolk, a new supply of water has been required at Bury's Hall, as the old well, which was 145ft. deep, showed signs of impurity. In the hope of finding water nearer the surface, "Professor" Stone was consulted. Having cut a forked branch of willow as a divining rod, he perambulated the grounds. The rod suddenly turned and fell towards him, when he declared that good water would be found at a depth of 25ft. Well-sinkers commenced work at the spot, and at 24½ft. an abundant supply of water was found, which soon showed a depth of 13ft. In the old well, which is only a few yards off, there is scarcely any water.

Sir Allan Sarle had a story of continued progress to tell at the meeting of the shareholders of the Sutton District Water Company last week. The capital expenditure during the half year amounted to £5509 11s. 6d., bringing up the total to £131,615, but as the heavy extensions which had been in progress during the past two or three years are now approaching completion, it was not expected that there would be very much more expenditure on that account for some years to come. The profit and loss account showed that the water rentals had increased from £8462 to £8803, but on the other hand the working expenses showed an increase of from £3408 to £4325, or nearly £1000. However, the increased expenditure did not affect the dividends, which were declared, as for several half years past, at the rate of 10 per cent. per annum.

The Public Control Committee reported to the London County Council last week that in consequence of the parish of South Hornsey being added to the County of London by the London Government Act, 1899, it is necessary that steps should be taken for the extension of the constant water supply system therein. The Committee recommended that notice be served on the New River Company to give a constant supply of water on and after the 1st day of July, 1901, to a district situated within the metropolitan borough of Stoke Newington bounded by an imaginary line running from a point in the centre of Seven Sisters'-road by Blackstock-road along the centre of Seven Sisters'-road to Green-lanes, thence southward along the boundary of the metropolitan borough of Stoke Newington to Church-street, westward along the said borough boundary to Green-lanes, and thence in a north-westerly direction along the boundary of the metropolitan borough of Islington to the above-mentioned point in Seven Sisters'-road. The recommendation was approved.

In compliance with the Standing Orders of Parliament, estimates have been prepared by the engineer acting on behalf of the proposed Ilkeston and Heanor Water Board showing the cost of the works proposed to be undertaken by that Board. The works comprise the sinking of an intercepting well communicating with the Meerbrook Sough, from which well an aqueduct will be laid down to a pumping station, to be called the Meerbrook Sough Pumping Station. From this pumping station another aqueduct will be laid down to a covered service reservoir, to be called the Chadwick Nick Reservoir. Two other aqueducts will also be laid down, connecting with the proposed covered service reservoirs at Shipley and Codnor Park, to be known respectively as the Ilkeston Reservoir and the Codnor Reservoir. The aggregate cost of these works is estimated at £128,000, which includes the purchase of the necessary property, and provides for contingencies. The further sum of £6000 will, however, have to be provided by the Corporation of Ilkeston and the Urban District Council of Heanor to acquire the undertaking of the Meerbrook Sough Company.

LIGHTING.

THE majority of the Colwyn Bay and Colwyn ratepayers have voted in favour of the purchase of the gas concern.

THE Dartmouth Urban Council has borrowed £20,000 from the Prudential Assurance Company for electric light purposes.

THE London County Council has agreed to lend the Poplar Borough Council £27,360 for an electric light installation.

THE Chard Town Council has decided to invite schemes and suggestions with a view to the public lighting of the town by electricity.

DURING the quarter ended December 31st last the electric lighting works at Canterbury yielded the Corporation a profit of £268 3s. 4d.

A LOCAL Government Board inquiry was held by Mr. Ducat at Newbury, last week, touching the application of the gas authorities to borrow the sum of £2500.

THE Taunton Town Council has decided to apply to the Local Government Board for sanction to a loan of £17,780 for the extension of the electric lighting system and plant.

CONSUMERS will be glad to know that the London County Council has unanimously decided to oppose the Gas Light and Coke Company's Bill. This action should be supported by every Local Authority in London.

THE new gasholder at the Holbeach Gasworks has just been completed, and has now been put into use. It has been erected by Messrs. Dempster (a well-known firm of gasworks contractors), under the supervision of Mr. J. G. Hawkins, manager of the large works at Spalding.

THE South London Electric Supply Corporation is making another generous offer to the inhabitants of Lambeth by undertaking to wire their houses for an equivalent of six eight-candle power lamps and supply the fittings, together with a prepayment penny-in-the-slot meter, absolutely free of all cost. There should now be no impediment to the general use of electric light for illumination instead of gas.

AT the half-yearly meeting of the Bedford Gas Light Company the directors reported that the new Bill had received the Royal assent, and acting under its powers, £3000 additional capital had been issued. The total cost of obtaining this new Act of Parliament exceeded £900. On the proposition of the Chairman, the report and accounts were duly approved and passed, and it was recommended that the dividends be declared at the usual rates as fixed by the sliding scale.

THE high price of coal was responsible for the somewhat unsatisfactory report submitted to the shareholders and profit sharers of the South Metropolitan Gas Company last week. But for the increased price of gas, Mr. G. Livesey explained, the deficiency in revenue would have been greater than the whole half-year's dividend. By the automatic action of the sliding scale the dividend payable was reduced by £19,796 in the half-year, so that, with £11,000 lost on the profit-sharing system and the reduced dividend of 5 per cent., the total burden arising from the high price of coal was £40,000 for the half-year. The Board, it was stated, contemplated a reduction in the price of gas of not less than 2d. per 1000 cubic feet from June. The report was adopted.

A DEPUTATION from the Watching, Lighting, and Fires Committee of the Aberdeen Town Council was in London last week making inquiries regarding two new systems of street lighting. One of these is the Sugg patent water pressure gas, and the other the Kitson system of lighting by petroleum. Both these systems are in use in London. Both methods are considered by some lighting experts to be superior to the electric light, in addition to being considerably cheaper. The deputation was most favourably impressed with the new illuminants, and it is possible that the manufacturers will be invited to fit up one or two lamps in Aberdeen as an experiment. During their stay in the Metropolis the deputation visited a number of works where mantles for incandescent gas lighting are manufactured. A visit was also paid to the central fire brigade station. On their journey north they stopped at Manchester and Liverpool to inspect the system of lighting there.

GENERAL.

THE Yarmouth Town Council has decided to expend £2280 for concreting various paths in the town and at Gorleston.

THE London County Council has decided to lend the Fulham Borough Council £24,145 for a dust destructor and street lighting.

THE report of the Medical Officer of Health for Redcar (Dr. Stainthorpe) indicates that the health of the town is very satisfactory.

THE Hastings Town Council has decided to apply to the Local Government Board for sanction to a loan of £2945 for street improvements.

THE Bootle Corporation contemplates loans of £8150 for Town Hall alterations and improvements, and £7000 for the cost of converting privies into water closets.

THE Leicester Town Council has resolved to not only purchase the local tramways, but substitute electric traction for horse-power. It is stated that the scheme will cost £500,000.

AT a recent meeting of the Aberystwyth Town Council the Finance Committee instructed the Town Clerk to secure the following loans:—Extension of promenade, £12,723; street improvement, £3046; and main sewer, £2900.

A LOCAL Government Board inquiry has been held at Pontypridd to inquire into the expenditure of £7930 for the erection of an isolation hospital for the district. There will be an administrative block, laundry block, and disinfecting block. The £9730 will include the cost of purchasing the site.

IN his annual report, Mr. Joseph Charlton, Sanitary Inspector to the Borough of Hartlepool, refers at some length to the housing problem. He says:—"The question of housing reform is one in which I take more than an official interest, and I am glad that a Committee has been formed to deal with this most complex and yet most important question. While I believe Hartlepool will compare favourably with other towns, it cannot be denied that the question of overcrowding and the necessity for new dwellings needs immediate attention if Hartlepool has to make progress or even maintain its position. The main question is the relief of the house famine by the provision of suitable houses at fair rents. If this were done, insanitary dwellings could be more readily closed, and cases of overcrowding dealt with, the respectable artisan would be prevented from becoming a slum dweller, and accommodation would be provided for those whose work brought them to the town."

DR. KING-WARRY, Medical Officer of Health for Hackney, says the *Times*, has, in compliance with the request of the Hackney Borough Council, prepared a report on the question of the housing of the working classes in his district. Dr. King-Warry points out that there were, according to the last census returns, 48,130 tenement dwellings in Hackney, and in one case it was shown that as many as eleven persons occupied a single room. The number of persons affected by overcrowding in Hackney is estimated at about 24,000. He thinks the following causes have exercised the largest influence:—(1) Inadequate building of workmen's dwellings; (2) increased cost of building materials and labour, leading to increased value of houses with corresponding rise in rent; (3) the disposition of late years to invest money in house property; and (4) the clearance of overcrowded and insanitary areas in other districts. Dr. King-Warry suggests that the difficulty might be met by the Borough Council's providing for the poorest part of the community a municipal lodging-house, to be under local control, and the price of accommodation to be fixed at the lowest figure sufficient to cover working expenses and a contribution to the sinking fund; while for those persons who constitute the poor of the district the Council might (*a*) purchase and convert any suitable large houses in the borough into tenement dwellings; (*b*) purchase land in the borough and erect suitable dwellings thereon at the cheapest possible rate; and (*c*) purchase land in the suburbs outside the borough for the same purpose. The charge should not be more than 1s. 6d. to 2s. per room per week to attract the poor classes. The dwellings for the very poor should not exceed 1s. to 1s. 6d. per week.

At the last meeting of the Hull and Goole Port Sanitary Authority reports were read from the Medical Officer (Dr. Wright Mason) and the Inspector (Mr. W. H. Crane) dealing with the recent outbreak of plague; the latter report describing the steamer Friary (which brought the plague cases to Hull) as being in a filthy condition. A circular had been sent to various Port Sanitary Authorities suggesting that the time had arrived when another effort should be made to induce the Government to pay out of the Imperial exchequer the expenses incurred by the Port Sanitary Authorities in taking precautions against the introduction into this country of cholera, plague, and yellow fever.

Last week a special meeting of the Sanitary Committee of the Middlesbrough Corporation was held for the purpose of considering the recommendations of a Sub-committee as to the disposal of night-soil. The Committee had several offers of barges submitted, and the Council, after considering the same, appointed the Mayor, Alderman Archibald, the Medical Officer, and the Sanitary Inspector, to arrange for the hire of barges required for taking manure out to sea for six months, from March 1st next. The Sub-committee having considered the cleansing and scavenging of the town, recommended (1) that during the six months when the manure is being taken out to sea the workmen be paid in accordance with the scheme of the Sanitary Inspector, and (2) that the Medical Officer and Sanitary Inspector be asked to consider and report on the question of the periodical cleaning out of the night-soil pans, and at the same time to prepare an estimate of the cost thereof. The recommendation of the Sub-committee was also adopted.

PERSONAL.

Dr. R. K. Brown has been appointed Medical Officer of Health for Bermondsey, at a salary of £500 per annum.

The salary of Mr. Charles Harrison, as Manager of the Accrington Gasworks, has been increased to £600 per annum.

Mr. James McMillan, C.E., has been appointed Engineer to the Motherwell New Waterworks at a salary of £350 per annum.

Mr. Chisholm, Peterhead, has been appointed Sanitary Inspector and Surveyor for Airdrie, at a salary of £200 per annum.

Mr. W. Curry, Surveyor for the urban district of Droylsden, has been appointed Surveyor for the urban district of Spennymoor.

Mr. C. W. Thompson, of Penrith, has been appointed Surveyor and Nuisance Inspector for Ripley, at a salary of £150 per annum.

The Local Government Board has sanctioned the reappointment of Mr. Shepheard as Medical Officer of Health for North Walsham.

Miss C. F. Stephens, of Bexhill-on-Sea, has been appointed Sanitary Inspector for the Bradford Corporation. There were twenty-four applicants.

The Local Government Board has sanctioned the reappointment of Dr. J. J. Jackson as Medical Officer for the Stanley Council, at a salary of £40 per annum.

Mr. Gerard J. G. Jensen, C.E., it is announced, will read a paper entitled "Notes on Certain Details of Drainage Construction," before the Society of Engineers on March 4th.

Mr. Archibald Dingwall has been reappointed Medical Officer of Health for the urban district of Kington, and Mr. Wm. Price has been reappointed Inspector of Nuisances.

The Richmond Town Council has appointed Dr. J. H. Crocker, Medical Officer of Health of Eccles and Port of Manchester, as Medical Officer of Health of the borough. The salary is £450 per annum.

Mr. Percy Cammidge, of the Yorkshire College, has been appointed to the newly-created office of Bacteriologist to the West Riding County Council, that body having decided to carry on researches into biological matters under the direction of its own Medical Officer.

The Poplar Borough Council has increased the salary of Mr. A. Blackman, borough electrical engineer, to £400 per annum, and that of Mr. F. W. Alexander, Medical Officer of Health, to £550 per annum.

Mr. Rowley Hill, son of the late Bishop of Sodor and Man, and late assistant-engineer to the Bromley Electric Light Company, Limited, has been appointed Manager of the Harrow Electric Light Company, Limited.

Mr. J. J. Crawford, Resident Medical Officer at the Victoria Hospital, Burnley, has been appointed Assistant Medical Officer at the Leeds Workhouse Infirmary, at a commencing salary of £130 per annum, rising to £150.

Mr. G. S. Perkins, pupil to Mr. T. J. Moss Flower, A.M.I.C.E., of 2, Victoria-mansions, Westminster, S.W., and 28, Baldwin-street, Bristol, has been appointed second engineering assistant to the Walthamstow Urban District Council.

Mr. Geo. Livingstone has been appointed temporarily as city Engineer and Surveyor to the City of Westminster. He is to continue to perform his duties as Surveyor of the Parish of St. George, Hanover-square, at a salary of £83 6s. 8d. per month on condition that he undertakes not to apply for the permanent appointment.

Mr. A. H. Shaw, who has been appointed as chief electrical engineer to the Ilford Urban District Council, and is shortly leaving Harrow, was recently the recipient of a handsome brass inkstand from the employés of the Harrow Electric Light Company, of which he has been chief since the works of the company were transferred from Messrs. Crompton and Co., who carried out the first installation.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

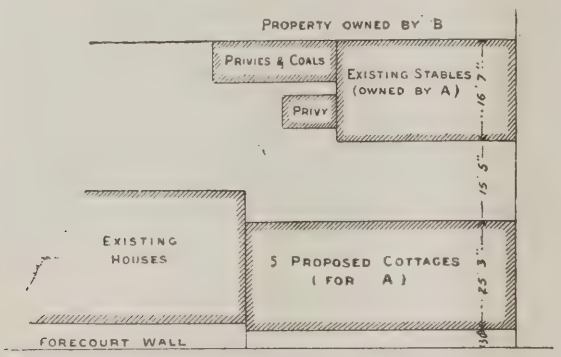
2094.—Food and Drugs Acts: Sanitary Inspector may obtain Samples.—"C. S. I." writes:—"Having been appointed Inspector of Nuisances to an Urban District Council, is it part of my duty to take samples of food, including milk and drugs? If so, is it necessary to have resolution of Council before taking samples, or should the samples be taken and sent for analysis and the matter reported? I have not been appointed Inspector under the Food and Drugs Act. Is this necessary? I understand the police have been taking samples in my district."

Answer.—If the Inspector of Nuisances has been appointed subject to the approval of the Local Government Board, his duties are defined by the General Order of the Local Government Board of March 23rd, 1891, and this order prescribes that the Inspector shall, when and as directed, procure and submit samples of food, drink, or drugs suspected to be adulterated, to be analysed by the analyst appointed under "The Sale of Food and Drugs Act, 1875," and upon receiving a certificate stating that the articles of food, drink, or drugs are adulterated, cause a complaint to be made and take the other proceedings prescribed by the Act. The querist is therefore in error in supposing that he has not been appointed Inspector under the Food and Drugs Acts, for every Inspector of Nuisances appointed under the order referred to is by virtue of his appointment an Inspector of Food and Drugs. If the Sanitary Authority require the Inspector of Nuisances to procure and submit samples of food, &c., they should direct him, as provided by Clause 8 of the order before referred to, by resolution or otherwise to do so.

2095.—Building Bye-laws: Open Space at Rear of Buildings.—"Surveyor" writes:—"I submit block plan showing five proposed cottages. The Model Bye-laws of the Local Government Board are in force in the district. The architect contends that according to Bye-law 54 he is not compelled to provide 20ft. between the rear of the houses and the existing stables (the houses are over 25ft. in height measured to half the height of the roof), inasmuch as he has provided 150 square feet—which space is free from any erection—as required by the bye-law; and he further maintains that the 20ft. specified refers to the distance from the boundary of the lands of a separate owner at B. He also wishes to bring the buildings forward in front as shown, in order to have 15ft. at the rear, but maintains the line of the existing forecourt walls. My contention is that the whole of the bye-law must be taken collectively, and that it is not sufficient to provide 150 square feet of space free from

erection, but that 20ft. must be allowed between the rear of the buildings and the boundary of the lands or premises immediately opposite—in this case the wall of the stables. Would you kindly give me a correct interpretation of the bye-law in question, and advise generally on the case?"

Answer.—The Local Authority are not enabled to approve the plans of the proposed houses, as they contravene the bye-laws in several respects:—(1) An open space is not provided exclusively belonging to each building, and of an aggregate extent of not less than 150 square feet, *i.e.*, that the open space for each house shall be distinct and fenced off separately. In this case the space at the rear is common to all the houses—see Bye-law 54. (2) By the same bye-law, where the height of a new domestic building is to be 25ft., the open space must extend from the rearmost wall of the building—whether it be a kitchen and scullery which project at the back, or the main back wall if no such projecting scullery is to be constructed—for a distance of 20ft. at the least. Such space must be free from any erection above the level of the ground except a water-closet, earth-closet, or privy, and an ash-pit. This distance must be, as clearly specified by the bye-law,



measured to the boundary of any lands or premises immediately opposite or adjoining the site of such (proposed new) building. In the plans submitted this distance must be measured to the wall of the stables nearest to the houses, which wall is the boundary of premises immediately opposite. As such distance is 15ft. 5in. and not 20ft., the bye-law cannot be complied with. The builders' contention that the distance referred to is to be the boundary of the lands of a separate or another owner is absurd. By such an interpretation it would follow that the back wall of the proposed cottage may be built to within 4ft. of the stable, as this would then leave 20ft. to the boundary of his premises. (3) The bringing forward of the main front wall of the houses as shown beyond the main front wall of the adjacent houses would be a contravention of Sec. 3 of the Public Health (Building in Streets) Act, 1888, rendering the builder liable to the penalties provided by the section, unless he first obtains the consent in writing of the Urban Authority.

2096.—Housing of the Working Classes: Dilapidated Houses. — "C. M." writes:—"There are some dilapidated cottages in my district, the rental of which varies from 1s. per week to £4 a year. In most cases the owners promise repairs, and so the tenants stay on in the hope that something will be done. Eventually, however, they are driven to leave, as the cottages become positively unfit to live in, and are often unsafe. Will you please advise whether an unfulfilled promise from an owner to make a cottage safe and habitable will release an occupier from the obligation to give notice?"

Answer.—If the cottages, being under a rental of £8, were not at the commencement of the tenancy in all respects reasonably fit for human habitation, then, and only in such a case, will the tenancy be determinable without notice. By Section 75 of the Housing of the Working Classes Act, 1890, it is enacted that in any contract made after the 14th day of August, 1885, for letting for habitation by persons of the working classes, a house or part of a house there shall be implied a condition that the house is at the commencement of the holding in all respects reasonably fit for human habitation. In this section the expression "letting for habitation by persons of the working classes" means the letting for habitation of a house or part of a house at a rent not exceeding £20 if the hereditament is in the metropolis, or £13 if in Liverpool, or £10 if in Manchester or Birmingham, or £8 if situate elsewhere. The section applies in the case stated by the querist, inasmuch as the rentals are less than £8, and if as beforementioned the cottages were not at the commencement of the holding in all respects reasonably fit for human habitation, then the tenants may repudiate the contract and cease to be liable in respect to it. Moreover, if a tenant suffers damage by reason of the insecure or insanitary condition which existed at the commencement of the tenancy, such damage may be recovered from the owner, notwithstanding that no guarantee, verbal or written, was given by the owner. In Walker *v.* Hobbs, 23 Q.B.D., 458, a husband and wife took three rooms in a block of buildings at Bermondsey at a rental under £20 per annum. At the time of letting, the plaster was insecure, and soon after some fell, and some months after more fell, which latter injured the female plaintiff. It was held that the plaintiffs were entitled to recover compensation from the owner.

TUBERCULOSIS—INFECTION, HEREDITY, PREVENTION, HYGIENIC TREATMENT.

By A. G. Young, M.D., Secretary State Board of Health, Maine, U.S.A.[1]

(*Continued from page* 160.)

Infection from husband to wife and vice versâ.—Behnke[20] relates the following case: A man with a phthisical tendency married a well and strong young woman. He died in five months from their marriage. After his death the widow began to show signs of consumption; nevertheless she married again and died of consumption a year and a-half from the time of her second marriage. This second husband married a widow, but soon showed unmistakeable symptoms of lung disease. He died of consumption a year and a-half later. About a year afterwards the twice widowed woman married a well and robust man. Three years later he died of consumption. Though the widow was well-to-do, the foregoing history was so remarkable that no man would marry her.

A large number of cases of conjugal tuberculosis might be cited here, but it must suffice to remark that the transmission of tuberculosis from husband to wife or from wife to husband is of quite frequent occurrence. On the other hand the instances are many in which infection does not occur.

Because it often happens, says Cornet, that tuberculosis is not transmitted from tuberculous husbands to their wives, or *vice versâ*, it is illogical to adduce these facts as evidence of the non-infectiousness of the disease. The closeness of the association of married life is often over-estimated. The work of the husband often keeps him away from his home more than half the time. In many cases separate beds or separate rooms are occupied. In many cases of consumption too, expectoration is slight or absent during the hours of rest, but is greatly increased during the hours of exertion. The husband may, therefore, expose his fellow-workmen, in shop or in factory, to much greater danger than he does the members of his own family. The exposure of the younger children to household infection is usually much greater than that between husband and wife.

Infection in offices, shops, and factories.—At the last French congress on tuberculosis, Dr. Oberthur[21] asserted that tuberculous contagion among the workmen in offices, workshops, and factories is very frequent—much more frequent than is often believed. Energetic measures are taken to preserve the lives of workmen from toxic products which surround them. It is none the less necessary to introduce measures against tuberculosis, which causes among the working population far greater ravages in a single year, than phosphorus, lead, mercury, fire-damp, and machinery in a century.

The next two following cases, selected from the many investigated by Cornet,[22] illustrate clearly the great danger to the fellow-workmen of consumptives who spit upon the floor of their workshops or places of indoor business.

Case 295. Admitted to the hospital in 1892. Bernard B., 29 years, single, a turner. The mother died in 1870 in childbed at the age of 42 years. The father died in 1875 from a disease of the stomach. Neither among the grandparents nor the brothers or sisters of the parents had there been a case of tuberculosis. A brother 25 years of age died of disease of the heart, and six brothers and sisters whose ages range from 32 to 50, are well.

In the shop where the patient worked from 1887 to 1892, a man O., died of consumption in 1889; then another workman who was much with O. died of the same disease. In 1889 the patient Bernard B. was troubled with spitting blood. Since 1891 his master, whose father died at the age of 61 of senile debility, and whose mother is well, died of tuberculosis. In the autumn of 1892 Fritz St., who had worked for four years as an apprentice in the shop, became tuberculous. The workshop is large and well ventilated, but these tuberculous persons had spit upon the floor, and the floor was swept dry.

Case 347. Admitted, 1892. Emil K., forty years, married, a cabinet maker. His father and mother are both living and well, the former at the age of seventy-six and the latter at the age of seventy-five years. The grandparents died at the ages of sixty-six and sixty-nine from other causes than pulmonary. A brother and sister, forty-seven and forty-nine years of age respectively, are well. One brother, twenty-six years old, died of an unknown disease. This patient, Emil K., works in the shop of a man by the name of Basch.

From 1869 to 1878 Basch worked in his small shop with Heymann. Heymann died of tuberculosis in 1878. Basch, with no hereditary tendency, showed symptoms of the disease in 1878, and died in 1889. A workman by the name of Gold died in 1880; another, Belke, in 1885. All of these persons died of consumption. Emil K., whose case led to the investigation of the history of this workshop, was supposed, early in life, to be scrofulous. He worked near Belke, and showed signs of infection in 1886 at the age of thirty-four. He died in 1892. Hanof, in whose family there previously was no history of tuberculosis, and has worked in the same shop since 1886, is now tuberculous. The eldest son of the master Basch, who took charge of the business after the death of his father, is, according to the testimony of his fellow-workmen, suffering from consumption.

Emil K., warned by his attending physician, and because his wife would not allow him to do otherwise, always spat, while at home, into a vessel containing water. His wife at the time of the investigation was forty-six years of age, in good health, as were also her two children, twelve and sixteen years of age.

In this workshop, where in the later years as many as thirteen persons worked, there were no spittoons, and it was their practice to spit upon the floor, which was always swept in the dry way. As in many other cases, there was here at first no indication of the sources of contagion of these patients. That was made evident only after an investigation of the condition of the workshop, and the conditions under which these persons worked took place.

Tubercle bacilli are found, as a rule, only in those places in which a careless or uncleanly consumptive lives or works, but, in the absence of knowledge of the chances of infection, we cannot rationally conclude that a man has not been exposed to infection. Many consumptives still at work, expectorating large numbers of bacilli, are unthought of by the laity as sources of infection, and are unknown to the physician until a careful investigation has been made.

Cornet presents statistics on the death-rates of various classes of workmen in confirmation of his statement that the consumptive patient, while he is able to work, endangers his fellow-workmen much more than he does his family, particularly when he and his fellow-workmen do their work in closed rooms.

As related by Professor Märfan,[23] he was consulted about the prevalence of pulmonary tuberculosis in an office in Paris in which twenty-two employés worked. In 1878 one of the number died of consumption, and since then deaths from phthisis followed each other in rapid succession. In four years ending in 1889 thirteen employés succumbed to tuberculosis. Investigation

[23] Rev. de la Tuberculose, v., 322. 1897.

showed that the hygienic conditions were bad—there were insufficient light and air supply. But the essential cause of the prevalence of the disease was attributable to the fact that the employés were in the habit of spitting upon the floor, and dried and pulverised sputum was put into motion in the air by the daily sweeping. The sweeping had been done in the morning, and the employés often arrived before the sweeping was finished, thus they were forced to inhale this infectious dust when it was most plentifully present in the air. In accordance with the advice of Dr. Märfan the old floor was taken up and burned, the place was repainted and otherwise renovated, a plentiful supply of spittoons were put in, and the use and care of these were kept under strict surveillance. The result was that, at the end of eight years, no new case of consumption had appeared among the employés.

Infection from transitory cases.—Infection is sometimes transmitted from transitory cases which may not be recognised as tuberculous.

Dr. Ducor[24] gives the history of two cases of infection from such a tuberculous attack in the mother. There was no history of tuberculosis on either side. The father, a man of forty-one years, had always been hale and hearty. The mother, forty years of age, suffered for a year from bronchitis which followed exposure to tubercular infection. She recovered, but the next to the youngest child, a girl of three years, had two tuberculous swellings, one of the hand and one of the knee. The youngest child at the same time had tubercular swellings of the cervical glands. By means of surgical and other help the children recovered. The seven older children in the family remained unaffected. Thus the only persons affected were the youngest two, who were naturally more exposed to the infection than their elder brothers and sisters with ages ranging from six to fifteen.

Outbreaks of tuberculosis in isolated communities.—In a few places tuberculosis is unknown; in some other places its introduction has occurred within the period of trustworthy history; in a larger number the movements of population have carried with them an increasing wave of tuberculous disease to the earlier or aboriginal peoples among whom hitherto there had been but a slight prevalence of the disease.

Dr. Frederick A. Cook, who accompanied Lieutenant Peary's Arctic Expedition, says that tuberculosis is very prevalent among the Esquimaux of South Greenland. In the Arctic Highlanders, however, tuberculosis is unknown, simply because the bacillus has never been carried to them.

In Terra del Fuego phthisis was absolutely unknown until an English missionary station was established in that district. The wife of the missionary, a consumptive opened a school, and soon many of the children succumbed to her disease.[25]

At the last meeting of the Congress of Tuberculosis in Paris, Dr. Ricochon[26] communicated the history of an outbreak of tuberculosis in a village where that disease had hitherto been of rare occurrence. He knew of three cases only before this outbreak, and they occurred more than fifteen years before. The village is situated on elevated and permeable calcareous ground. The houses are neat and well ventilated. The water supply comes from springs, and is of excellent quality. The people are cultivators of the soil, habituated to a life in the open air.

Case 1.—In 1894, a young woman of thirty years of age had a swelling of her foot which eventuated in an ulceration which resisted repeated cauterisation and other treatment, and which assumed a character of a tuberculous ulceration. In 1896 she was attacked with pulmonary tuberculosis and died one year later. Thus far neither her husband, her two children, nor the domestics of her house, have shown signs of contamination; but the neighbouring houses have presented cases of tuberculosis.

Cases 2 and 3.—In the next house, a young woman of twenty-eight years had a dry pleurisy of the right side in 1896, which came on insidiously and which threw her into a condition of marasmus for three months, which appeared to be of tuberculous origin. During this same period of time, a child, six years old, who had measles two months previously, and who had remained in a feeble condition since then, was attacked with tubercular meningitis and died.

Cases 4 and 5.—In the house situated next in order, a woman of thirty-eight was attacked in March, 1896, with a grave form of tuberculosis of the cervical vertebræ from which she died in November. Meanwhile, one of her children, a little girl of ten years, was attacked with dry pleurisy of the right side, from which she recovered.

Case 6.—In the next house on the same street, a child of five years died after an illness of eight days of tuberculous meningitis. Some months before it had measles.

Cases 7 and 8.—In a house upon another street near the cases two and three, a woman, forty-nine years of age, whose health hitherto had been perfect, began to cough at the end of the year 1895, and died of pulmonary phthisis, July, 1896. Some months afterwards, her husband, previously strong and vigorous, began to cough, and died of pulmonary phthisis in May, 1897.

Case 9.—The sister-in-law of these last two patients, one of the most robust women of the country, who, off and on, took care of them during their illness, was attacked with a dry cough and a pain in the back of her shoulders. There were signs of the dry pleurisy over the posterior superior two-thirds of lungs. Her condition at the end of two years still remained serious, though there was slight amelioration. She had profuse sweats, hectic fever, and other evidences of tuberculosis.

Case 10.—A girl eighteen years of age, whose paternal line had a slight tuberculous taint (an uncle died of tuberculosis at the age of twenty-two years) but the health of this young woman had always been good until she contracted bronchitis in the course of which she had two very pronounced attacks of hemoptysis. Submitted to a vigorous treatment, she improved and has gained in weight.

Case 11.—A woman of thirty years, who had had but one child, and whose health had always been excellent, and whose parents died of old age, as most of the parents of the preceding patients had, has for some weeks past had a serious effusion into the left pleura, which I have already tapped twice. Disseminated bronchial rales on the right side are of a suspicious nature.

Case 12.—A young man of thirty-two years living near the first case, whose health had habitually been good, began to cough and had a serious hemoptysis last May. Upon examination there were already crackling rales at the summit of the right lung. He became emaciated and lost strength. He was submitted to an intensive treatment with creosotol, phosphate of lime, and chlorid of sodium. There has been an improvement in his appetite, and, in the last few weeks, an improvement in weight.

Here, says Dr. Ricochon, are the facts. After an absence of tuberculosis for fifteen years in a village, and after the re-appearance of a case of that disease, ten or twelve other cases followed in the houses of the nearest neighbours in less than a year. The map of the village, which the doctor presents, showing the location of the infected houses, added to the interest of his paper. The cases all appeared upon or near one line of streets, while no cases appeared in the houses grouped along the one other street.

ANNUAL REPORTS.

Eston.—The annual report of the Medical Officer of Health (Dr. F. Fulton) was presented to the Eston Urban Council last week. During the past year there had been 393 births registered and 240 deaths. Refering to the number of deaths due to diseases of the respiratory organs, the Medical Officer stated that he had to repeat what he said last year, that owing to the nature of the employment of so many of the population this was likely to continue. The sudden change of temperature from the works to the cold and damp of the outer air, more especially in the cases of those badly clothed and ill-fed, must affect most injuriously the lungs, the air passages having been already more or less irritated by the solid particles suspended in the air of the works. This, in his opinion, was a more important cause than any specific microbe, which had been so much talked about, as producing pneumonia in these parts. There had been 37 cases of tuberculosis as against 28 last year, and the Medical Officer asked, as they are preventible diseases why are they not prevented. This might be done, he stated, by boiling the milk used immediately.

Perth.—Mr. Duncan Cumming, Sanitary Inspector of Perth, has just issued his report for the year ending 31st December, 1900. It states that there were 170 complaints as to nuisances registered, and 68 discovered by him at periodical inspections, showing a total of 238, as compared with 158 the previous year, being an increase of 80. All these nuisances were dealt with, and in almost all the cases the authors, on being informed concerning them, took prompt steps to have them removed. Two hundred and thirty-three notices were served under Section 19 Public Health (Scotland) Act, as compared with 93 the previous year. Two samples of water were taken from the river Tay during the month of June—one from the west and the other from the east side of Moncrieffe Island, near the filter bed. The samples were submitted to Messrs. Tatlock and Thomson, City Analysts, who reported that the samples were quite clear, and were quite free from even the slightest trace of contamination by matter of the nature of sewage, and they were of opinion that they were well adapted for drinking, cooking, and general dietetic purposes. A sample of water was also taken from a mineral spring called Shaw's Well, near Craigie Burn, as it had been suggested to the Town Council by a citizen that the site of this valuable spring should be marked in some way or another by the erection of a fountain. The report of the analysts stated that the water was quite free from even the slightest trace of contamination by sewage matter, and was in every respect well adapted for drinking and general dietetic purposes. The number of inspections made of common lodging-houses during the year was 159, as against 91 the previous year. The houses were found clean and in a fairly satisfactory condition, but in many cases were old buildings. Sixty-nine inspections were made of dairies and cowsheds, compared with 109 in 1899. A case of anthrax occurred in one of the byres. Prompt measures were at once adopted for isolation of cattle and stopping the sale of milk, and the byre was disinfected. No further outbreak occurred. No diseased meat had been seized. The inspections of the slaughter-house number 157, as against 108 the previous year. Seventy-five samples of food, &c., were purchased during the year, an increase of fifty-six over last year, and, with the exception of one of milk, all were genuine. A conviction was obtained in the case of the milk. Mr. Cumming had eleven samples of beer analysed on account of the reports that beer in several counties in England contained arsenic, but the result of the analyses showed no arsenic. Twenty-two inspections were made to workshops, as compared with fifteen the previous year. Nine complaints were received from her Majesty's Inspector of Workshops, and all these were promptly attended to. The total number of cases reported under the Infectious Disease (Notification) Act, 1889, was 160, and the number of cases reported the previous year was 380—a decrease of 220. The epidemic of scarlet fever declined during the month of February, and almost entirely disappeared in May and June. That disease still showed the greater number of cases, although during the month of December only two cases were notified. The small-pox hospital, which had been opened for the reception and treatment of scarlet fever patients on 12th August, 1899, was finally closed on 23rd February, 1900, and the services of the nursing staff dispensed with. The interior was thoroughly disinfected, cleaned, and made ready for the reception of patients. The number of patients admitted during that period was fifty-five, and the total cost (including clothing, bedding, and furniture) was £391 17s. 7¾d., and the actual cost per patient £5 12s. 4½d. Reference was also made to the arrangements with the Infirmary Directors regarding the treatment of infectious diseases. There were 1162 statutory and other notices issued, while the total number of inspections under the Public Health Acts was 1883. The report concludes with a reference to the precautions against bubonic plague and the disinfection of infected clothing, &c.

Truro.—Dr. Bonar, Medical Officer of Health to Truro Rural District Council, in his report for 1900 states that the district comprises 23 parishes, with an acreage of 84,157, and a population in 1891 of 22,557. The births were 256 males and 268 females, equal to a rate of 23·14 per 1000 of the population; and the deaths, 196 males and 220 females, a rate of 18·37 per 1000. Natural increase, 108; infantile death-rate, 99·2; zymotic death-rate, ·57. Deaths from zymotic diseases —Scarlet fever 2; enteric or typhoid, 6; diphtheria, 1; erysipelas, 1; diarrhœa and dysentry, 3. Classification of deaths from other diseases—Epidemic influenza, 20; enteritis, 1; phthisis 35; other tubercular diseases 8; cancer, 20; bronchitis, 49; pneumonia, 16; pleurisy 1; other respiratory diseases, 1; cirrhosis of liver, 2; premature birth, 8; parturition accidents, 2; heart disease, 45; accidents, 11; all other diseases, 184. Inquests held during the year, 27. Of the above total (416) 52 died under 1 year; 13 between 1 and 5 years; 17 between 5 and 15; 19 between 15 and 25; 112 between 25 and 65; 203 over 65. There were 235 cases of infectious diseases notified during the year:—Diphtheria, 5; erysipelas, 27; scarlatina (scarlet fever), 184; enteric fever, 17; continued fever, 1; puerperal fever, 1. The cost of the working of the Notification Act during the year was, to each of the 23 parishes in the Union, per week, about 5½d. Diseases prevalent during the year were measles, scarlet fever, and mumps. Special sanitary work and expenditure—Drainage, £57 8s. 11d.; water supply, £35 10s. 3d. Water supply considered deficient at St. Agnes (being provided for), Perranporth, Wheal Rose, St. Mawes, and Rose. Drainage considered imperfect at Chasewater, Mount Hawke, Perranporth, and St. Mawes. 526 notices to abate nuisances were issued during the year; 29 plans of new buildings were presented to the Sanitary Committee; certificates of occupation granted to 22 new houses under Public Health Act, 1878; all elementary schools inspected, limewashed, cleaned, &c., where necessary; a large number of dip wells supplied with pumps, many cleaned out and repaired; privies and ashpits, between 50 and 60 built, and over 90 repaired; slaughter-houses and dairies inspected during the year; three walls were condemned during the year, and analyses of three waters made.

THE HOUSING QUESTION.

MEETINGS AND MOVEMENTS.

Mansion House Council.

Mr. H. Leonard presided at the monthly meeting of the Mansion House Council on the dwellings of the poor. The report showed that insanitary conditions had been attended to in ten districts. The number of houses dealt with during the month was 835, and 346 had been reported to the Authorities.

Debate at Chelmsford.

A discussion on this question was opened by the Rev. J. D. S. Perry-Evans at a meeting of the Chelmsford Debating Society, Mr. C. Williams presiding.

Mr. Parry-Evans, who moved a resolution in favour of Government action being taken in respect of the housing of the poor, as the increased cost of building sites and building materials was out of proportion to the advance in wages, gave an outline of the miseries which are produced by overcrowding, some of the instances he cited being the result of his personal investigations in London in the neighbourhood of Drury-lane. He dealt successively with the causes of overcrowding—the difficulty of obtaining building spaces, the necessity of the workers living near their employment, high rents, the immigration wave from the country town-wards, and the demolition of houses for improvements of various kinds; and he showed how these factors in the problem operated in bringing about the deplorable evils that are universally admitted to exist. In concluding a very able address, he urged that a remedy lay in the delegation by Government of a full measure of authority to Local Councils to provide dwellings for the workers, and to erect cheap lodging-houses for the migratory classes.

Mr. J. A. Webb seconded the motion.

Mr. F. W. B. Stocker proposed an amendment to the effect that no Government action was necessary, as, under the Housing of the Working Classes Act, 1890, Local Authorities had power to deal with the question.

Mr. J. O. Thompson seconded the amendment; and Messrs. G. H. Coleman, H. Barnes, W. Bewers, P. H. Soames, and W. Cutts also took part in the debate.

Eventually the amendment was carried.

Inquiry at Prescot.

Mr. H. H. Law, one of the Local Government Board's inspectors, held an inquiry at Prescot into an application by the Prescot District Council for the confirmation of a scheme of improvement under the Housing of the Working Classes Act, 1890. There was a good representative attendance.

It appeared from the details given by the officials of the District Council that the scheme included the demolition of a considerable number of alleged insanitary dwellings and the construction of a new street, 36ft. wide, from High-street to Eccleston-street, two of the principal thoroughfares of the town. It was explained that the amount of outstanding loans at present was £1900; the assessable value of the district was £19,288; and the population was estimated at 8000. The Council did not intend to touch the question of the rehousing of the people who would be displaced; but preferred to leave it to individual enterprise, which, it was thought, would meet the requirements. The affected area No. 1 of the proposed improvements comprised 4658 square yards, and the population, including lodgers, was 166. The gross rental was about £302. The estimated total cost of the improvement for that area was £5574 11s. 10d., including the construction of the new street, compensation, &c. The area No. 2 comprised 590 square yards, with a population of 32, and the estimated cost of the work was £700 3s. 7d.

Dr. E. F. Hall, Medical Officer of Health, said the present buildings on the affected areas were a danger to public health, and, in his opinion, the improvements were necessary.

Mr. H. Leyland, surveyor, said the surplus land would hold twenty-two new houses after the proposed new street had been made.

Mr. F. W. Halsall remarked that there was not at present one empty house in either of the areas.

The Inspector said that pointed to the fact that it was incumbent on the Local Authority to provide dwellings for the people who would be displaced. No matter how poor the people were, they must be provided with cottages.

Dr. Hall, in reply to a question, said he thought the land gained by the improvement would be too valuable for ordinary cottage property.

Mr. E. Tracey, secretary of the British Insulated Wire Company, and Mr. James Berry, of Prescot, also spoke in favour of the scheme.

At the close of the inquiry, the Inspector proceeded to visit the areas included in the scheme.

Deputations to the President of the Local Government Board.

A deputation, consisting of members of the National Housing Council, and several prominent trades unionists, waited upon Mr. Walter Long, President of the Local Government Board, with reference to the housing of the working classes. Mr. W. C. Steadman explained that they desired the Board to extend the period for which loans were granted. At present sixty years was the limit allowed; but buildings were being erected by the municipalities which would last two hundred years. If the Board would extend the period, municipalities would be able to reduce the rents, and materially contribute to the better housing of the poor.

Mr. Long, replying, said the difficulty of dealing with the question was that people wished to live where they found employment, and did not realise the conditions under which they lived. There was considerable misapprehension respecting the attitude of the Local Government Board. As regarded the extension of time, Parliament had been stricter than the Board, and had thought that any extension would involve great risk, which, in the interests of the ratepayers, should not be incurred. The Department had to see that the money of the ratepayers was so spent that the interests of all classes were reasonably protected. Were they sure the extension of the period of the loans would give them the relief they desired? As to the building regulations, some confusion prevailed. In London they were imposed under the London Building Act, and in rural districts by the Local Authority, framed as model bye-laws. Before these were objected to it should be shown they were unreasonable and unwise. Their object was to secure the erection of good buildings, of good sanitary character, and with proper air space. Nothing would give him greater satisfaction than to be able to lessen the difficulties of the Local Authorities. The fact that the London County Council was making a large step in this direction showed that the new powers under the Act of 1900 would be of advantage. With regard to the need for improved means of communication, trains would follow the population, and there was reason to suppose that we were on the verge of a vast improvement in locomotion.

The deputation thanked the right hon. gentleman and withdrew.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

NEW YEAR'S PRESIDENTIAL ADDRESS.

By Dr. J. B. Wilkinson, D.P.H., &c., M.O.H. County Borough of Oldham, and Consulting M.O.H. County of Huntingdonshire.

(*Concluded from page* 169).

THE SLOP CLOSET.

Probably the earliest form of closet, which has any characteristics similar to the ordinary slop closet, is that which may still be found in country districts, viz., a seat placed over a small stream or on the immediate bank with a slope leading from under the seat down to the stream. Though a very ready and convenient way of disposing of refuse, it is not a method which can find any word of approval. A very similar method was the original slop closet, except that the stream of water has its place taken by the smaller stream of sewage and slop water coming from the adjacent house. For purposes of general description the slop closet consists of two forms, one known as the "automatic" and the other in which the sewage simply flows through the pan. The simplest form of the latter is a seat placed over a basin or large pipe, which is connected with a trap beneath leading into the sewer, and a pipe conveying the sewage opening into the closet just above the trap (Fig. 1). The excreta falls into the trap, and

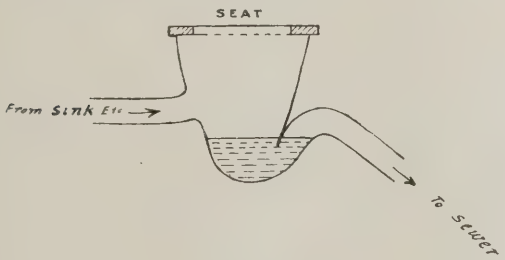

Fig. 1.

the slop water, &c., as it comes from the house carries it away into the drain. At least that is what it ought to do, but I think the general experience is that this action is by no means so regularly carried out, and that frequent blockages of the trap occur, necessitating some hand flushing to carry off the refuse; the fault of this form of closet being that the sewage does not flow with sufficient force to carry with it the solid material. This kind of closet has been introduced under various names, perhaps the earliest was known as the Southport closet, followed by the Fowler closet, and later by the Birmingham closet, the latter being associated with the name of Dr. Bostock Hill. An earlier form than any of these was the Bristol eject, in which a brick basin lined with cement was connected by a trap to the sewer, and the closet had to be flushed by hand, and therefore is hardly a true

WASTE-WATER CLOSET.

The next stage in the improvement of this class of closet was with the intent of storing up the water so as to give sudden and forcible flushes of water to thoroughly clear the closet and trap beneath it. A cistern was attached into which the slop water ran, and which, when full, emptied itself rapidly by means of a syphonic arrangement, very similar to some of the automatic flushing cisterns for clean-water trough closets and latrines in use to-day. The objection to this arrangement lay not in the closet, but in the slop water, which often contained pieces of paper or straw, grease, or other solid material sufficient to stop the action of the syphon, which was eventually for this reason discarded. I am not sure, but I believe it is due to Mr. Duckett, of Burnley, that the present improved form of automatic stop closet was introduced. The improvement consisted of the introduction, in connection with the closet, of a basin into which the sewage falls, and which when full tips over, discharging its contents suddenly into the closet, and flushing out any material which has accumulated in it, and then regaining its position for filling again. The basin, or "tipler" as it is called, usually holds about three gallons of water, but in closets on the latrine plan considerably more. The tipler is placed in such a position that the slop water, bath water, and, if possible, rain water, will flow into it. This improved closet is now made under several names, each varying somewhat in their arrangement. Practically there are, however, two types, one in which the tipler is placed in some position *between* the closet and the sink, and the other in which the tipler is placed *in* the closet and immediately under the seat, so that it receives in addition to the water the excreta, and discharges both, when full, into the trap beneath. As a type of the former, the closet made by Messrs. Duckett, of Burnley, may be taken as the one best known; and of the latter, that made by Messrs. Day, of Wolverhampton, and known as the "Stafford" closet. As far as I am aware, this is the only closet in which the tipler is placed under the seat itself; in all the others the tipler is in some position between the closet and the water supply, generally the sink.

A brief description of the arrangement of a Duckett closet is as follows :—The slop stone pipe and, if possible, the rain-water pipe, discharge on to a dish stone, placed over an ordinary syphon trap, from which a 4in. or 6in. drain leads to the closet. The closet itself consists of a large earthenware receptacle, in one end of which the tipler is fixed, and a pedestal is fixed over the other half. The trap leading to the sewer is immediately under the pedestal. The drain from the slop pipe discharges into the tipler. Originally the tipler was placed under the slop pipe and away from the closet, but it was found that the force of the flush was broken by the flow through the drain.

The special feature of the Duckett closet (Fig. 2) is

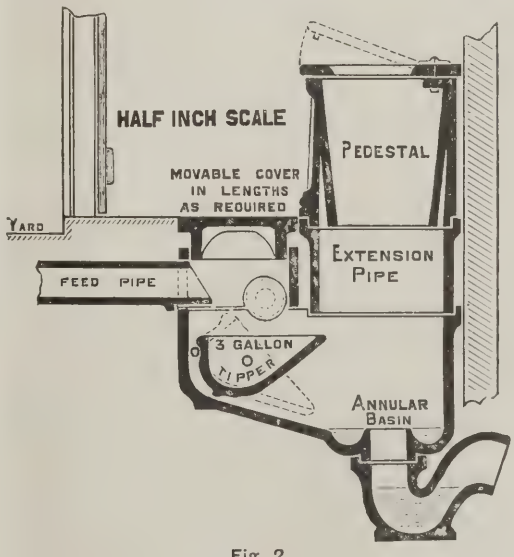

Fig. 2.

that the trap leading to the sewer is a comparatively small one, and its opening is surrounded by a small circular water channel called the annular basin, which retains water after flushing, so that excreta falling from the pedestal either drops into the trap itself or into the

water in this channel, there being only the narrow edge of the trap between the two.

The tipler is usually of a three-gallon capacity,and the discharge from it is projected on to the annular c hann at a tangent (Fig. 3), so that the flow takes a circular course round the trap until meeting a stop, when the water goes over into the trap, carrying with it any

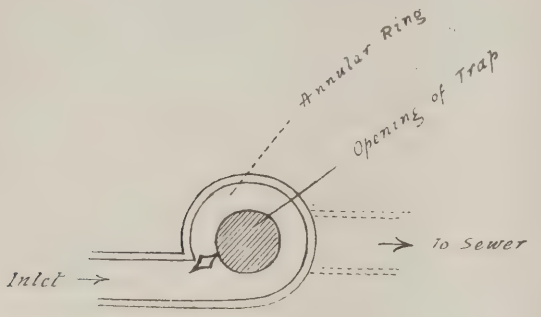

Fig. 3

solid material which may have accumulated. Several forms of seats can be used, but the best and simplest form is the pedestal with an ordinary hinged seat, or in low-class districts a pedestal with a wood rim screwed to the edge of the pedestal.

The tipler is best placed beneath the closet floor and covered by a removable flag or iron cover, so that the tipler can be easily reached in case of damage. Another feature of this form of closet is that in some the lower opening of the pedestal is specially contracted into a quatrefoil shape. This prevents large articles reaching the trap, and does not much impede the progress of excreta. It, however, leaves an angle beneath this contraction which cannot be readily cleaned. A later improvement has been brought into use by the same firm in which the slop water, when discharged from the tipler, enters the basin of the closet round the rim in a circular manner, and is very similar to a rim-flushed clean-water closet. This form was designed to keep the whole of the closet in a clean condition.

This class of closet must, however, be in a building immediately adjoining the room in which the sink is placed, and so close up to the side of the house. The tipler can be placed immediately under the sink in the house, or supported in brickwork immediately outside the house wall. The latter seems to me much the most preferable arrangement. This kind of closet has been styled the "Perfect" slop-water closet, and, indeed, it appears difficult to suggest any improvement in it.

A somewhat similar form of closet to the latter has been arranged by Mr. Dibble, of Birmingham, which also, I am informed, gives great satisfaction. In this closet the tipler discharges on to a grid, through which the water flows before reaching the closet pan. This grid prevents any solid articles being discharged into the pan, but at the same time the force of the flush must be considerably reduced.

Messrs. Whittaker and Co., of Blackburn, construct a closet very similar to the closet first described, the chief difference being that the tipler, though placed close to the closet, is yet in a separate receptacle, and is perhaps in consequence slightly less liable to become foul. Messrs. Oates and Green's closet is somewhat similar, except that the tipler falls backwards, and is claimed by the makers to give a more even flush. Other makers of these closets are Messrs. Clark, Hargreaves, Adams, Stevenson, and Place. The Stevenson closet has a removable disc placed over the trap to intercept large articles. In some of these closets the excreta falls into a pan which contains water, and the opening into the sewer is at the side or back of the closet. In these a special opening to the trap is made behind the closet for the purpose of cleansing, but as this has generally to be some depth below the ground it is not easy to get at.

In Messrs. Day's closet the tipler is placed directly below the seat, and is somewhat larger in anterior and posterior diameter than the pedestal opening, so that all solid matter falls directly into the tipler itself, as well as the slop water; and as the tipler becomes full the contents are discharged directly on to the opening of the trap leading to the sewer (Fig. 4).

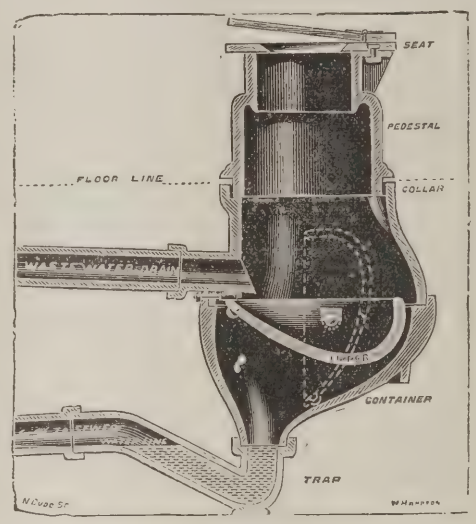

Fig. 4

The next point is to consider the relative advantages and disadvantages of these two types of closet, and the advantages and disadvantages of the slop-water closet itself. The advantages of the slop-water closet may be summed up as follows:—

(1) No extra water supply is necessary, and a head of water is not required.

(2) There is little or no probability of a slop-water closet freezing.

(3) There is less liability of getting out of order than an ordinary water-closet in low-class districts, unless they are hand-flushed by an attendant.

(4) An advantage over the conservancy methods by the absence of soil and surface pollution in and around the closet, and the removal at once of the excreta from the neighbourhood of dwellings.

The disadvantages are:—

(1) The closet is not so clean as a water-closet, the sides being liable to become foul.

(2) A liability to become blocked or broken.

(3) The sewage is fouler.

In discussing these matters it must first be stated that the slop closet can and is only meant for use outside dwelling-houses, and in a separate erection, though this erection may join the house. No opening from one to the other, except for the passage of the slop pipe, or pipe from the tipler, should be permitted.

Where a sufficient water supply can be obtained, I have no hesitation in saying that the clean-water system is far preferable; but in many of the larger towns there is great anxiety over the water supply, and the Authorities are negotiating for increased sources of water, and it is an absolute necessity to husband the present supply and not entertain further sources for its distribution, and a general conversion of privies or pan closets to the clean-water closets could not be entertained. In such towns as these the slop water closets would not be barred for the same reason. I have already spoken of the risk of freezing in outside water-closets, and in slop-water closets there is not this liability. Much of the discharge from sinks, &c., is of a temperature

sufficient not only to prevent freezing, but also to thaw any slight frozen surface which may have occurred during a severe night. In certain districts it is found that ordinary water-closets are constantly being broken, cisterns damaged, and chains pulled off and taken away; and though various articles—stones, bricks, brushes, ashes, &c.—are constantly being put into these closets, on the whole I think there is less liability for slop-water closets to get out of order in such places than clean-water closets.

That the slop-water closet even in its foulest condition has an advantage over the cesspools and privy middens which still exist in several of the finest towns of our kingdom, I think few will deny. As to their preference over a well-conducted pan or tub system that is open to some argument. From investigations I have made, my own experience is that, both in relation to typhoid and epidemic diarrhœa, these diseases are about twice as prevalent in houses supplied with pan closets as in those supplied with slop-water closets, and about twice as prevalent in houses supplied with slop-water closets as in those to which clean-water closets are attached; the slop-water closet being in its relation to these diseases a sort of half-way house between the pan closet and the ordinary water-closet. Though some of these closets do become very foul through want of proper care, in few cases are they equal to the exceedingly foul condition of a similar class of pan closets, and certainly not where ordinary privies or cesspools exist. In places where closets are liable to improper use a regular system of inspection—daily if necessary—ought to be instituted, and the tenants rather than the owners of the houses made to pay for removing blockages which are due to improper materials being put down.

That the sewage of a town in which a large number of waste-water closets exist is fouler than where the town is supplied by clean-water closets is perfectly true, but the question is if this increase of impurity interferes to any great extent with the treatment of the sewage. All towns, if they carry out the duties assigned to them by law, are required to treat their sewage before discharging it into the watercourses. It has been shown that a purely domestic sewage is the easiest to treat, and it is a point open to argument if, where bacterial systems are in use, the addition of excremental material which is loaded with "breaking-down" bacteria to the sink water (much of which is sterile) will not hasten more than impede the resolution of the organic matter in the sewage. In places where the supply of water is very limited waste-water closets would not be advisable, but where a daily flow of fifteen or twenty gallons per head exists they will be found to act satisfactorily. Without recommending any special make as the best, the arrangement of the trap in the Duckett closet has advantages over many others, in that it is directly under the seat, and can be thus easily reached for the purpose of removing any materials causing a blockage. The method of discharge in this make, too, which causes a circular flow round the trap, appears to be an advantage over a direct discharge on to it, while the placing of the tipler in a separate chamber, as is found in Whittaker's make, renders the tipler chamber less liable to be fouled by excrement. In respect to the Day pattern, where the tipler is directly under the seat, it ought, from its construction, to be a much cleaner closet, but it has two great disadvantages. One is the great liability of the tipler being broken by heavy articles being dropped upon it; and the other the frequency of the blockages. These blockages are usually of a trivial character, easily remedied, and largely due to paper, cotton-waste, &c., getting round the pivots on which the tipler works.

In 1899 the total percentage of blockages which occurred in about 2000 closets of various patterns was 16, and the average cost of putting each closet right was 1s. 6d. In 1900 the percentage of blockages was 14, and the average cost of removing the obstructions about the same. If the cost of these obstructions is averaged among the whole number of waste-water closets it amounts to an average of 2½d. for each.

To summarise the conditions under which waste-water closets will be found to act satisfactorily, they must be placed (1) outside the house; (2) in positions where there is, at least, a moderate flow of slop water; (3) they must be properly fixed, and the drainage made perfect in the first instance; (4) there must be a satisfactory scheme for the treatment of the sewage. In districts where householders are careless and dirty, a regular system of inspection should be instituted, and in some of these localities even a daily visit by the Inspector will be necessary to ensure a continuous and satisfactory working.

THE NEED FOR A MINISTRY OF PUBLIC HEALTH.

At a meeting of the Lancashire and Cheshire branch of the Sanitary Inspectors' Association, held in Manchester, Mr. Fred Scott, secretary to the Manchester and Salford Sanitary Association, read a paper on this subject. He urged that a Ministry of Health was in the highest degree necessary. In the Transvaal war, he said, about 7000 men had been killed in action or died of wounds, and almost double that number had died of disease; and in the United Kingdom there were 120,000 preventable deaths every year. Yet we accepted such a state of things as if it were inevitable. The most convincing proof of the inefficiency of our system of health adminstration was the fact that such an enormous death-toll for disobedience to the laws of health was still taken. The public mind was satisfied with the assurances given from time to time of apparent progress as indicated by reduced mortality from certain diseases or success in coping with a threatened epidemic. Yet all the time we were, so to speak, dwelling in a charnel-house, and progress towards that ideal time when a case of zymotic disease in any community would be regarded with almost as much wonder as the reappearance of a specimen of the old British wolf must needs be slow while we regarded the present fearful death-toll as inevitable. It must be admitted that under the present system an excellent organisation for the prevention of disease had been developed, but what was the use of machinery if the hands of those who could and would work it were more or less tied? Mr. Scott indicated several ways in which a Ministry of Health would be of service. For one thing, there would be something like uniformity in the bye-laws of Local Authorities, and Medical Officers and Sanitary Inspectors would be directly responsible to the central authority. A Health Ministry would have a special care for the perfecting of health legislation, and perhaps one of the first things to be done in this direction would be to change the "mays" in Public Health Acts into "shalls." In illustration of the evil results of the present system, Mr. Scott stated that the building bye-laws in Manchester would, if strictly enforced, prevent the erection of any more "jerry" property in the city, yet in some of the suburbs speculative builders were now erecting streets of houses, which in a generation or less must be become slums. In this matter Local Authorities, he submitted, ought to be controlled by a strong central authority.

At the last meeting of the Carlisle Town Council the Baths Committee submitted plans of proposed Turkish baths, which the Council approved and adopted, and authorised an application to the Local Government Board for leave to borrow £1985 to carry them out.

MANCHESTER LADIES' HEALTH SOCIETY.

ANNUAL MEETING.

Last week the annual meeting of the Manchester Ladies' Health Society was held in the Lord Mayor's Parlour at the Town Hall. Mrs. Hardie presided over a numerous attendance.

Mrs. Redford submitted the annual report, which gave a satisfactory account of the work accomplished during the fortieth year of the Society's existence. There were fewer new developments than would have been the case if the funds had not been at so low an ebb. The expenditure had increased and the income had not kept pace with it. Another serious want was that of ladies to superintend the districts. In the South Ancoats division, the inspection of consumption cases became steadily a more considerable part of the health visitors' work. In the Angel-Meadow district lectures on temperance, home life, food, &c., had been given. The number of children sent into the country through the assistance of the children's holiday fund was fourteen, a much smaller number than usual. In the Chorlton-on-Medlock district many insanitary houses had been made habitable, defective roofs had been repaired, and drains and broken flags attended to. Twenty-five children were sent into the country for three weeks through the children's holiday fund. In St. George's district since Easter, two large baths had been put up in Collyhurst recreation room, and there was an average weekly attendance of twenty-five. There were no Corporation baths very near. Seventeen children had been sent away by the holiday fund. In St. Simons, Salford, a beer-house and full-licensed house had been closed. In Silk-street district, forty-five children had received benefit through the country holiday fund.

The balance-sheet showed a balance in hand of £8 12s. 5d.

Dr. Rhodes, in moving the adoption of the report, eulogised the useful work which was being carried on by the Society in spreading a knowledge of the causes of disease, and teaching people the first principle of sanitation. He deplored the prevalence of insanitary dwellings in Manchester, and said he rejoiced that the public were awakening to the injury which was being done to the taxpayer in consequence of the amount of suffering which went on through the insanitary conditions under which the people lived. It was largely in consequence of the slum life of the city that the death-rate of Manchester was so high as to be a disgrace to the city. He mentioned that in Angel Meadow the death-rate was within a decimal of 51 per 1000 of the population, owing to the improper conditions under which they lived. It had been officially reported that the evil was owing to the dirty habits of the people. He did not believe that was so. In Manchester the people were no dirtier than in other towns, yet the death-rate here was enormously larger. The working classes of England were losing £31,000,000 a year through the non-payment of wages during illness, and that any improvement was now becoming noticeable was largely owing to associations such as that.

Archdeacon Wilson, in seconding the motion, remarked that typhus was largely due to dirt, and it was therefore imperative that the people should be taught the importance of sanitary methods.

Mrs. Hardie, commenting on the remarks made, said it was very often the tenants who were to blame for the insanitary state of the houses, and the Society's visitors tried to teach the people how to keep their grids clean. In some neighbourhoods, however, that was a very difficult thing indeed.

The motion was carried.

Miss Burstall, in the course of an address, gave her own impressions of the Society's work, and spoke of the great value of women's work in relation to public health. She could not imagine a sphere of work more fitting for women than that taken up by the Health Society.

The meeting closed with votes of thanks.

National Health Society.

OFFICIAL TRANSACTIONS.

Once again we have to record the success of the National Health Society's diplomées and students in securing public appointments. Miss Hutchinson, who has just been appointed as Health Lecturer at York, received her training under the Society and holds its diploma, while Miss Finola Sullivan, who now holds an appointment as Sanitary Inspector in Dublin (Pembroke Ward), is also a diplomée of the Society. It will be remembered that only last week we chronicled the success of three other of our diplomées, so that it will readily be seen that the Society's training receives marked consideration and appreciation in the selection of candidates for public appointments.

A course of lectures on Anatomy and Physiology by Dr. Squire will be commenced on Tuesday, March 12th, at 53, Berners-street. These lectures form part of the training for the Society's diploma. Further particulars and details will be given at a later date.

On Monday next, March 4th, Dr. Cantlie will give the last lecture of his course on "First Aid" at 53, Berners-street. These lectures have been well attended throughout, and much appreciation has been shown for the individual teaching and attention given by the lecturer to each member of the class.

Lectures at Schools.—One of our lady lecturers is now engaged in giving a course of "First Aid" lectures to the pupils at a large boarding school for ladies at Southbourne-on-Sea. The Society is always glad to receive applications for such lectures, as it is felt that the instruction given must be useful among a number of girls in teaching them to act in an emergency, and in some measure to rely upon themselves.

Elementary Examinations.—We are again receiving numerous applications for these examinations from various counties. Yorkshire, Bedfordshire, and Lincolnshire are all arranging for the examination of a large number of candidates during the next few weeks, while several smaller examinations are also in progress.

The Housing Committee of the Bermondsey Borough Council presented a report last week as to the present position of the Fulford-street and Braddon-street, Rotherhithe, improvement scheme. The estimated net cost of clearing the area, which measures 68,000 square feet, and making new roads and sewers was £29,120, of which the London County Council had agreed to contribute one-half. The number of persons who would be displaced was 550, but plans had been agreed upon with the London County Council and the Local Government Board for the erection of four model block buildings, capable of accommodating upwards of 800 persons. Thirty-nine claims had been settled out of a total of 48, representing a sum of £22,102. Application had already been made to the Local Government Board for the appointment of an arbitrator to deal with the disputed claims, and also with a large piece of vacant land in Braddon-street, of which the owner could not be found. Mr. G. R. Askwith had been appointed arbitrator, and the committee recommended that the hearing take place at the Rotherhithe Town Hall.

MUNICIPAL ELECTRIC LIGHTING.

On Thursday afternoon last the Mayoress of Fulham (Mrs. Cornwall) formally switched on the electric light at the electricity supply works which this enterprising muncipal borough has erected near the end of Wandsworth Bridge.

That the occasion was of something more than local interest was evinced by the presence of invited guests from other municipalities who took a keen interest in the proceedings. More important still, it marked the final triumph of yet one more London municipality in a field of enterprise which has in not a few instances been surrendered to private Corporations without serious pretext.

From the records of the now defunct Fulham Vestry, in possession of Mr. W. J. H. Denselow, the acting Town Clerk of the Borough, it appears that soon after an electric lighting scheme was first contemplated five or six years ago, two private companies made a bold bid for Provisional Orders. The Vestry, however, showed fight and carried the day against their would-be rival, and thus the borough ranks among the sixteen Local Authorities in the County of London which—apart from the powers the London County Council possess in respect of the electric lighting of the Victoria Embankment and Westminster and Waterloo Bridges—are authorised to supply electricity within their own areas.

The Fulham supply works really combine an electrical generating station with a refuse destructor and a disinfector. The destructor, which is of the Horsfall type, consists of twelve cells, room being left for the addition of four others when required, and the heat developed by the burning of the refuse is utilised, so far as it will go, in raising steam in the main boilers. It is estimated that 40,000 tons of refuse will be passed through the destructor yearly, and taking its calorific value as one-twentieth that of good steam coal, this arrangement will save the Borough Council the cost of 2000 tons of coal per annum. Coal, however, will also be needed; the supply is brought up the Thames, on which the station site abuts, lifted from the lighters by a steam crane, weighed in an automatic Ingrey weighing machine, and raised to the bunkers by an electric elevator. The furnaces have Vicars mechanical stokers, and the Babcock and Wilcox water-tube boilers are supplied with water from an artesian well on the premises. The generating plant consists of three sets of two-phase alternators of Swiss design, but made by the General Electric Company at their Manchester works; each is of 300 kilowatt capacity at from 2800 to 3000 volts, and is driven by a horizontal compound condensing engine of the low-speed Corliss type, made by Messrs. J. Musgrave and Sons, of Bolton. The speed of the alternators is 93·7 revolutions a minute, and the frequency is 50 a second. There are also three continuous-current dynamos by the same makers for exciting and other purposes, each coupled directly to a Musgrave enclosed high-speed engine, and three Ferranti rectifiers for use in connection with the public supply circuits. Of the cables, which were made by the British Insulated Wire Company, some thirty-six miles are already in place, and earthenware ducts have been laid for forty-eight miles. The high-pressure current yielded by the main alternators is transformed down at five sub-stations, and the public receive their supply at 200 volts, both a single-phase and double-phase current being available for motors. The charge is to be 5d. per unit for lighting, and 2½d. per unit for power, no charge being made for meter rent. No "free-wiring" contracts have been entered into, but it is satisfactory that applications equal to about 10,000 eight-candle power lamps, or one-third of the total capacity, have already been received. It is also satisfactory that the various contracts were entrusted to British firms, and the work was carried out by British labour.

LINCOLN CITY SURVEYOR ON SANITATION.

At Lincoln Church House Mr. R. A. MacBrair, A.M. Inst. C.E., Mem. San. Inst., Lincoln City Surveyor, gave a lecture on "Some Dangers to Health; Points in Sanitation." The lecturer referred at length to the composition of air, and gave figures showing the evil results of non-ventilation and of improper ventilation. He specially condemned the various—now, fortunately, old-fashioned—systems of down draughts, and by means of special diagrams showed such systems to be much worse than useless. Boyle's system he considered as good as any possible. Slides were then thrown on the screen illustrating how defective drainage is injurious, and how such defects are not only quite avoidable, but how that the systems which are without these defects are just as simple to lay as any other. Then, after a description of disease germs, and the way they increase and spread, Mr. MacBrair went on to explain how their propagation may be checked and the germs themselves destroyed by means of chemicals and various other disinfecting processes. The great sanitary question of all municipalities was, of course, the disposal of the town's sewage. Various methods have been tried in America, where there were very large, fast moving rivers. The sewage was dumped into them, and soon oxidised without at any time being a danger to health. But in the inland towns of England this method was not possible, and other ways had to be adopted. The best known was the treatment of the sewage by chemicals and its conversion into a fertilising agent, but the best and latest treatment was by means of a septic tank, in which the germs, instead of being destroyed, were cultivated and set to neutralise one another, the cultivation of the germs being carried out on a coke lining to the bacteria beds. In Lincoln the sewage system had been of inestimable benefit to the inhabitants, the death-rate having been reduced from 25 per 1000 in 1848 to 14 per 1000 in 1900, this, for the present population, being a saving of 500 lives per year. Sub-Dean Leeke, in proposing a vote of thanks, said this was a most important subject, and one that should be taken up by everyone if only for the sake of strengthening the hands of the Council in their efforts to make the city as healthy as possible.

Mr. M. H. Footman, Chairman of the Sanitary Committee, seconded the resolution, and referred to the Corporation farm at Washingborough, which, according to the report of the Local Government Board Inspector, was as good as any in the country, Mr. MacBrair being one of the pioneers of the bacteria bed system. He also said that a sixpenny rate had been spent during the past year on the farm, and as much would be spent this year, but then Lincoln would be as fully equipped for the disposal of sewage as any place. It was really a matter worth doing, since improved sanitation has, according to the insurance actuaries, increased the prospect of life by 1½ years in the case of men and 2¾ years in that of women, and each life is of the value of £157 per year to the State.

The Maldon Town Council and Rural District Council have combined for the purpose of erecting and maintaining an isolation hospital, and an inquiry was held by Mr. W. W. E. Fletcher, M.B., last week into an application for the formation of a Joint Hospital Board. The cost of the proposed building is put down at about £6000.

Sanitary Inspectors' Associations.

NATIONAL UNION.

A QUARTERLY meeting of the National Union of Sanitary Inspectors was held at Oswestry on Saturday, 23rd inst. There was a good attendance of members, including Messrs. W. Bland, chairman of Union; N. Coates, hon. treasurer; A. Jno. Hughes, hon. secretary, North Wales District Centre; J. T. Quinton, hon. secretary, North-Western Centre; H. H. Spears, hon. secretary of Union; and representatives from Liverpool, Manchester, Birmingham, St. Helens, Bolton, West Bromwich, Stafford, Wednesbury, Rhyl, Higher Bebington, Lower Bebington, Wrexham Rural, Oswestry, Oswestry Rural, Denbigh, Connah's Quay, Formby, Bangor, &c.

The party assembled in the Council Chamber, Guild Hall, Oswestry, where the official reception took place. The Mayor (A. T. Daniel, J.P.), who wore his chain of office, was supported by Dr. Aylmer Lewis, chairman of the Sanitary Committee; a large number of the members of the Corporation; Mr. J. Parry Jones, Town Clerk; Dr. Beresford Hope, Medical Officer of Health; and Mr. G. W. Lacey, Borough Engineer, and others.

The MAYOR tendered a cordial welcome on behalf of the borough, and expressed his hope that the visit of the National Union to Oswestry would prove to be both interesting and instructive. The town they were visiting was not one of mushroom growth, as their charter of incorporation was 503 years old, but nevertheless they prided themselves on the fact that they were thoroughly up to date in sanitary matters. He would ask the chairman of the Sanitary Committee, Dr. Lewis, to give them a short description of the special work they had undertaken as regarded the bacterial disposal of the sewage.

Dr. AYLMER LEWIS said that he personally was very pleased to support their Mayor in his welcome to the delegates. They had many visitors at their bacterial works—Engineers, Medical Officers of Health, members of Councils, and sanitarians generally—and all who had hitherto visited the district had gone away satisfied that the Oswestry Corporation were on the right track. The disposal of sewage had been a most serious question for them to deal with at Oswestry. Expert advice had been taken, and they were informed that an expenditure of from £20,000 to £30,000 would be necessary. Their late engineer, Mr. Wynne Roberts, now of Capetown, went into the matter, and as a result they constructed out of revenue some bacterial beds which were working in a most satisfactory fashion.

Dr. BERESFORD HOPE, Medical Officer of Health, also spoke, and claimed that he was one of the oldest Medical Officers of Health in the country, he having been in office for something like thirty-four years. In the course of a most racy speech he alluded to the steps that had been taken to purify the air and subsoil of Oswestry. He held that Sanitary Inspectors and elementary teachers were the two most useful professions in the country.

Mr. W. BLAND, chairman of Council, acknowledged the cordiality of the reception, and moved a vote of thanks to the Mayor and Corporation, which was enthusiastically adopted.

The quarterly meeting was then held, the routine business including the election of the following new members:—Messrs. J. L. Clarke and A. Williamson, Liverpool; A. E. Chertham, Manchester; C. R. Billingham, John Franklin, and Fred. Sowerbutts, Stockport; O. H. Williams and R. Holden, Blackburn; R. W. Marshall, Fenton; and J. H. Pearson, Broadstairs, Kent.

Mr. Thomas Morrell, Darlaston, was also elected as an Associate Member.

The CHAIRMAN then called upon Mr. G. W. Lacey, C.E., Borough Engineer and Surveyor, to read his promised paper on "Oswestry Bacterial Sewage Disposal Works and Sanitation."

Mr. LACEY pointed out that the population of the district was about 10,000, and was increasing at a fairly rapid rate. The town was sewered practically throughout, and water-closets were general throughout the town. The water supply, which came from the Welsh hills, was very good. After describing the history of the well-known bacteria beds, which he said had cost about £2000, the average cost of maintenance being about £220 per annum, he said the average purification effected was as follows:—Albuminoid ammonia, 80·5 per cent.; and oxygen absorbed, 88·4 per cent. Their vital statistics were also very satisfactory Their death-rate for 1900 was 16·0, the zymotic rate being 0·41. It appeared that with the exception of Newport, they were the healthiest town in the county of Salop. Eight cases only of diphtheria and typhoid had been reported during the two years 1899 and 1900, and in 1900 only one death had occurred from typhoid, and none from diphtheria. All the ashpits had been abolished, and for the last four years there had been a daily collection of house refuse.

A discussion on the paper was opened by the CHAIRMAN, who was followed by Messrs. A. JOHN HUGHES, W. WOODWARD, H. EDWARDS, N. COATES, J. T. QUINTON, JOHN EVANS, and the HON. SECRETARY, a hearty vote of thanks being passed to Mr. Lacey at the close.

Mr. LACEY thanked the members for the vote of thanks, and briefly replied to the various questions raised.

The party then proceeded to the sewage works by brakes, where a demonstration was given by Mr. Lacey.

At the conclusion of the inspection the party were driven to the Queen's Hotel, where tea had been provided by the hospitality of the Mayor and Corporation, the function terminating a most successful meeting.

CORRESPONDENCE.

(*To the Editor of* THE SANITARY RECORD.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

WHAT CONSTITUTES A SANITARY INSPECTOR?

SIR,—I should like to know through the medium of your paper if any man acting as Sanitary Inspector for a district can describe himself or use the title Sanitary Inspector without obtaining some sanitary certificate. I think it is very unfair if such be the case, when we find men appointed without any certificate whatever. It is fully time the sanitary body sent a Bill to Parliament for Guardians and boroughs that nothing but qualified men be appointed. Now, I will give you an instance. I live in a rural district consisting of twenty-six parishes. The Sanitary Inspector (uncertificated) was a Guardian of his board previous to appointment, and brought up as a farmer. He simply resigned his position as Guardian, and was appointed Sanitary Inspector. He does not live in one of his inspecting parishes. He is an auctioneer and valuer, and has no mode of conveyance. He receives a salary of over £40 per annum. It looks hard for men who have studied and spent money, and who have to fight against such.—

Yours faithfully,
ASSOC. SAN. INST.

February 23rd.

BOTH the Millom and Bootle Rural Councils have announced that unless certain stipulated conditions are accepted they will offer all possible opposition to the Barrow water scheme.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

I observe that an American has invented a machine which it is claimed will supersede snow ploughs and the like for clearing away snow. This apparatus is described as a furnace on wheels, fed by petroleum and supplied with an iron fan-shaped shield which projects in front of a series of burners a few inches above the roadway, the snow on which is rapidly dissolved by the heat radiated downwards by the shield. A set of rotary brushes sweeps the melted snow into the gutters and leaves the street perfectly clean.

It is interesting to observe that the Corporations both of Leeds and Manchester have been simultaneously carrying on experiments to test the practicability of the purification of sewage by bacterial methods, and that in each instance they are satisfied as to the efficiency of the method. It appears that in each case septic tanks were considered necessary adjuncts to aid in liquefying the solids in the sewage prior to its being run on the contact beds. Continuous filtration by sprinklers has not been found successful, which confirms the opinions I formerly expressed in this column, and which have been combated by one or two correspondents. Open septic tanks, it is asserted, give equally as good results as closed ones, and at the most it is not expected that such tanks will require emptying more than once a year. The sewage of Leeds is an exceptionally difficult one to treat bacterially, owing to the excessive amount of iron present in it—indicative of its industries—amounting to as much, I believe, as four tons per day. This material silts up the coarse beds hitherto used, and it is hoped to obtain a material which will not be affected to the same extent as the clinker which has been previously utilised for such beds. These difficulties only serve to show how that dogmatising in the domain of sewage treatment is impracticable and foolish, owing to the varying character of the sewage of different towns. Such difficulties can, however, be overcome, especially when the subject is tackled in such a thoroughgoing scientific manner as that followed at Leeds under the able chairmanship of Alderman Harding—who is by profession a civil engineer—in conjunction with Mr. Hewson, the borough engineer, and who are also assisted by eminent chemists.

Adaptability of conditions as regards sewage treatment to inland towns is very necessary, but it does not agree with the practice of the Local Government Board, who appear to attempt to enforce one system—land treatment—under all circumstances. Possibly the Board will learn wisdom by-and-bye. I should add that the experiments referred to, and others which I could name, have shown that bacteria beds constructed to a depth of 10ft. and 12ft. give excellent results as regards purification.

The bye-laws of Local Authorities with regard to new buildings, as is well known to surveyors, prohibit any timber or woodwork being placed within 15in. from the upper surface of the hearth of any chimney, and in order to meet this requirement it is a general practice to construct such hearths in concrete, a segmental arch being turned from the trimmer joist to the wall. In order to facilitate this mode of construction, and to ensure thoroughly sound work, I would advise my readers to acquaint themselves with Moore's Steel Hearth "Bridge" boxing, which is made, as its name implies, of steel $\frac{1}{8}$in. thick, and of varying spans and width on which to carry the concrete without fixing any centering. The steel plate, which is convex in form, has a flange on one side which rests on the chimney breast, and on the other side is a flange for bolting to the trimmer joist. It is readily fixed, extremely effective, and reasonable in price. Messrs. Statham and Sons, contractors' merchants, are the sole agents for the manufacturers, viz., Davies Brothers, Abenbury Works, near Ruabon.

I have often been at a loss to understand why Rural District Councils neglect so greatly to protect their districts against fire by failing to organise and maintain fire brigades. This neglect is unfair to the ratepayers of their district, for in the event of a fire occurring on their premises the cost of the fire brigade from a neighbouring urban district has to be paid by the owner of the premises damaged, who has already by the fire suffered sufficient loss. Such ratepayers are in a much worse position than those dwelling in an urban district, for the latter cannot be called upon to pay the costs of attendance of their own brigade.

A Rural District Council is enabled to obtain urban powers under Section 171 of the Public Health Act, 1875 [which incorporates the provisions of the Towns Police Clauses Act, 1847 (Sections 32 and 33) relating to the provision of fire engines and firemen] and no better example of the successful application of these powers can be found than that afforded by the Sunderland Rural District Council. It appears from the excellent annual report of the brigade compiled by Mr. J. C. Wilson, the energetic secretary to the brigade department—and who is also deputy Clerk to the Council—that in all the parishes, save one, a paid and regularly-drilled brigade, under a superintendent and deputy-superintendent, with a well-equipped fire station and manual engine, now exists. An admirable set of rules is in force containing instructions for drill; particulars as to the exact locality of each hydrant; instructions as to attendance at fires, &c. Effective means for summoning each member in the event of an outbreak is in force, and generally the organisation of the brigade system throughout the district, under the able control of Mr. Wilson, is about as efficient as any I have come across. I commend the perusal of Mr. Wilson's report to the officials and members of Rural District Councils, in the hope that it may stimulate other Councils to emulate their example.

Writing of fire protection for villages, I have frequently observed that some villages which are dependent entirely upon wells for their domestic water supply suffer most seriously in an outbreak of fire from the inability of a brigade—when it does attend—to secure a sufficient supply of water from which to pump. Such a difficulty may very frequently be overcome, in many instances which I have come across, by the construction of an artificial pond across a small watercourse at any point within a quarter of a mile of the village, and all villages dependent upon their water supply from wells should make and maintain such an artificial pond if practicable. Where, however, no such stream of fresh water is available, then the effluent from the village sewage works, or, as a last alternative, sewage which has been partially freed from solid matter by straining or rough screening, may in an exigency be utilised. By the formation of responsible and well-organised parish fire brigades only will proper measures, such as those indicated, be taken to prevent that serious destruction and loss to property in rural districts which is so frequently chronicled, and which might, with a little forethought and provision, have been avoided. Senex.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

Journal of Sanitary and Municipal Engineering.

FEBRUARY 28, 1901.

THE SMALL-POX EPIDEMIC IN SCOTLAND.

THE epidemic of small-pox in Scotland continues to spread over an ever-increasing area, and the disease has now made its appearance in a number of places that were previously exempt. There is hardly one of the larger towns in Scotland where cases have not occurred. But in Glasgow, the principal seat of the epidemic, and to which its ramifications elsewhere are almost all traceable, the reports are more favourable, indicating that the outbreak is steadily on the decline. At a meeting of the Town Council last week the convener of the Health Committee reported the number of cases then in hospital to be 387—a considerable decrease on previous reports, and the number has since then been still further largely reduced. It was also mentioned that the percentage of deaths was 3·52 in the case of vaccinated persons, and 46·30 in the case of persons who had not been vaccinated—a statistical result which should carry conviction with anti-vaccinators. Re-vaccination has been largely taken advantage of in Glasgow, 240,000 adult persons having undergone the operation, but as the total adult population is 560,000, it will be seen that more than half the population have still failed to respond to the appeal of the Corporation.

In Leith an excellent report on the subject has been made by Dr. W. Leslie Mackenzie, who, after his resignation of his position as Medical Officer of Health, continued to supervise the work of the department until the date of his successor's entering on office. He emphasises the importance of early isolation, and says that to the educated care and vigilance of the profession, and to the rapidity of action whenever a case was discovered, they owe the fact that, although during the six years of his tenure of the Medical Officership small-pox had been imported into the burgh on sixteen separate occasions, infecting twenty-three houses, yet in no single instance had it broken bounds, or spread beyond the house in which it was in each instance discovered. He did not well see how this record could be improved upon. The system he had followed, he proceeds, had been very simple, but very thorough; immediate isolation, immediate disinfection, and vaccination of immediate contacts, relentless daily and hourly pursuit of possible contacts, daily supervision at home or in hospital for fully a fortnight, and during that fortnight he had spared neither man nor beast. He had blotted out the distinction between day and night, and the reward had always been a clean bill at the end. In these words we have the administrative ideal to work up to. So far as the individual is concerned, we cannot do better than quote the words of Dr. Matthew Hay, of Aberdeen, that "it is necessary to impress on the public mind that the one proved preventive of small-pox is vaccination, followed by re-vaccination if the person is above ten to twelve years of age. There is no fact in the whole region of preventive medicine which stands upon a surer basis than the preventive effect of vaccination upon small-pox."

The Value of Veterinary Inspections.

AN interesting decision has been pronounced by Sheriff Orphsot, of Edinburgh, which illustrates the value that is to be placed on veterinary inspections of cattle at public sales. A cattle dealer was charged under the Public Health Act of 1897 with having been the owner of a cow which was deposited in the sale-yard of Messrs. Oliver and Sons, Edin-

burgh, for the purpose of sale, and which was then unsound and unfit for food. The evidence showed quite clearly that the animal was suffering from tuberculosis, and after slaughter the organs were found to be affected with tuberculosis to a large extent. But the defence put forward was justifiable ignorance, and reliance on a Veterinary Inspector's examination. The accused said he had bought the cow the previous day at Messrs. Oliver's public sale at Hawick, where all the animals were previous to sale inspected by a Veterinary Inspector; and the veterinary surgeon corroborated this, stating that he had observed nothing wrong with the cow. The Sheriff was satisfied that the accused did not in point of fact know the condition of the cow; but the real question was whether he could not have known by the exercise of reasonable care. In making the purchase he relied upon the fact, known in the trade, that the animals exhibited in Messrs. Oliver's yard for sale were, previous to sale, examined by a veterinary surgeon, and he consequently took it for granted that none but sound animals would be sold. But considering that on the occasion in question the surgeon had examined thirty cows and about 200 sheep, the examination must have been of a somewhat general character; there was no special examination of any particular animal. The question then came to be whether a purchaser was, from the point of view of the Public Health Act, entitled to rely on such an examination by the veterinary surgeon. To decide that question in the affirmative, the Sheriff said, would open the door for the introduction of animals which might pass the veterinary surgeon's examination in the sale-yard, but which might yet be, as that cow was, in a condition dangerous to the public health. He could not, therefore, accept the reliance on that examination as taking the place of the reasonable care required by the Act of Parliament, and must accordingly convict. The decision is an important one, and from the point of view of the public health, quite unimpeachable.

Phthisis in Schools.

The Secretary of the Board of Education, in reply to a query from the Kingston-on-Thames School Attendance Committee inquiring how they are to act in the case of children with a tendency to consumption failing to attend school, and whether special classes should be established for consumptive children, writes:—"I am directed to state that the Board of Education are advised that a tendency to consumption is in itself no bar to attendance at school. But a child suffering from actually developed phthisis ought to stay away, as fit only for medical treatment, and as infectious and dangerous to other scholars. In doubtful cases, where no medical certificate is forthcoming from the home, your committee should take steps to obtain one." This attitude seems reasonable enough. But it is to be hoped that the education of consumptive children will never be insisted on to the extent of providing special classes for their benefit. The preservation of human life is even more important than education, and the hygienic conditions of crowded schoolrooms are not likely to eradicate the disease. When the danger to others is considered, there can be no question that the proper place for a consumptive child is at home, and not at a public school. Those with a tendency that way are better in the open air. There is no object to be gained in educating a child and sacrificing its life in the process.

London's Latest Scheme.

At the meeting of the London County Council on Tuesday the Housing Committee gave some particulars of the great scheme which, we were told, had been for some time in preparation. The site selected is at Tottenham, and would appear to be well served on one side of the estate with train and tram communication direct to the heart of the City. There are stations on the southern side from which the Council hope to secure the running of workmen's trains at nominal rates. The area of the ground proposed to be secured is about 225 acres, and upon this the Committee estimate that 5779 cottages may be erected, capable of housing 42,500 persons. At present, however, only a portion is to be developed, upon which accommodation for 33,000 persons will be provided in 4750 self-contained two-storey cottages, and 2000 more will be provided for in tenements over shops. The cottages will be of various classes, and each cottage will have its own garden. The number of persons to be placed on the site will not crowd the land unduly. The depths of the various cottage plots will be generally greater than the bye-laws of the Local Authorities require, and forecourts will in all cases be provided. The frontages to the main roads are very suitable for shops, and about 10½ acres of land will be given up to this purpose, upon which about 250 shops will be erected, and from these a considerable income could probably be obtained should the Council decide itself to build the shops. It will be necessary to widen Lordship-lane for the construction of the proposed tramway, and the shop plots have been made of sufficient depth to allow of this being done. Open spaces will be left for public gardens and playgrounds. Many other interesting details were given, and finally the Committee reported that the estimated cost would be £1,530,858. This is based upon the idea that no charge shall be imposed upon the rates. The Committee deem this a "harsh" condition, but we cannot agree with them. That the cost of the land should be spread over a longer period than that of the buildings is a just contention, and will be endorsed by every thoughtful person, but we do not see in the refusal of the Government to grant this division of expenditure any reason for charging one class of ratepayers for housing another. If the working classes have been able to struggle against the extortionate rents of jerry builders and "grasping landlords," surely they will gladly pay the lower charges which a municipality can let at sooner than make themselves a burden to others. The middle classes of this

country are fully prepared to bear their share of the legitimate cost of government, and that is heavy enough, without imposing fancy charges upon them to satisfy the clamour of a few theorists, who ever shirk any practical exemplification of their pet scheme.

An Optimistic Report.

There is an interesting paragraph in the annual report of Dr. Samuel Kirby, Medical Officer of the Hoxne rural district in East Anglia. So much has been written on the distressful condition of the labouring classes in this part of the country, that it is quite cheering to come across something of a brighter nature. Dr. Kirby is of opinion that labourers' dwelling-houses in his district are slowly but surely being improved. "Four old houses have been pulled down, but much yet remains to be done; at present the supply exceeds the demand, and the would-be tenant has a chance of choosing the better cottage as a residence. There are many old cottages in the district which are untenanted, unsightly, and dilapidated, and which before they could be inhabited would have to be put into a proper state of repair—a course expensive and perhaps unsatisfactory. Undergoing as we are a process of depopulation, we cannot expect to see many new cottages erected, the space accommodation must be sufficient, or we should have more cases of overcrowding. The general condition of the agricultural labourer has very much improved during the last few years, and, in a great number of cases where this is not apparent, the cause lies with the person who should be benefited. Whether the light railway, which is intended to run through part of the district, will, when completed, add to the welfare of the district remains to be seen." Better homes, improved conditions, and light railways, may yet make for the salvation of the East Anglian labourer.

Salaries of M.O.H.'s.

It would be well for Medical Officers of Health as a body were all mayors as equally far-seeing and liberally-minded as Alderman Stillings, the Mayor of Pudsey. At a recent meeting of the Pudsey Town Council the question of the Medical Officer's salary came up for discussion in his reappointment, and a proposal was made to increase the stipend £100 per annum. In supporting this step the Mayor said:—"Clearly it was their policy to secure and to maintain throughout the borough a 'clean bill of health' and the best sanitary conditions, so as to encourage building operations for both dwellings and business purposes, which would be followed by an influx of new residents, and, as a necessary consequence, would increase the rateable value. This was no mere dream. It was the goal at which they had to aim, and they must make their plans with prudence, forethought, and courage to accomplish this end. In his (the Mayor's) judgment the Medical Officer would play a very important part, and he was persuaded that the wisest course for the Council would be to place that functionary in a strong position. He ought to be upheld in every useful health reform he brought forward; he ought to be encouraged to suggest reforms; he ought to be placed in such an independent position that he could feel free to inaugurate any reform and correct any evil without being subject to the risk of personal anxiety of dismissal from service. He should not be a mere chronicler of disease and insanitary conditions, but he should feel that he had the Council at his back in his efforts to sweep away without fear or favour anything and everything prejudicial to the public health. Therefore, in his opinion, they should pay something like an adequate salary for the responsible position which he held." Unfortunately the opinion of the Council was not unanimous, the resolution only being carried by nine votes to eight; but, all the same, the Medical Officer has the satisfaction of getting the increase. If the point of view put forward so admirably by Alderman Stillings was generally taken to heart, Medical Officers of Health would be placed in a much more satisfactory position than they are at present. But it is well to know that the representatives of the positions are gradually being better appreciated, and they are bound to be more so as education and enlightenment increase and the status of public bodies is raised.

Prejudice still to be Overcome.

When the Borough Councils came into existence in the metropolis we hoped that many of the old prejudices and narrow practices would pass away with the old Vestries. But it would appear that in Lambeth, at any rate, there still lurks an objection to the employment of women as Sanitary Inspectors. Last week the Council received a recommendation from its Officers Committee to the effect that instead of "increasing the annual increments of the Sanitary Inspectors in consequence of extra services, we recommend the appointment of a female Sanitary Inspector to relieve them of the pressure of these extra services by taking some of their other duties." The recommendation had been referred to the Medical Officer of Health, who reported strongly for the lady. He pointed out that in Lambeth there had been registered 740 workshops, with 1303 workrooms, wherein 4324 were employed. Of these, 2539 were women and girls, who certainly would be better looked after by a female Inspector. In addition, there were many shops wherein women and girls alone were employed. Women and girls were more likely to talk to and confide in female than male Inspectors. Moreover, a female could inspect infants' and girls' schools, visit the houses of the poor, visit tenement houses or houses let out in lodgings, and work amongst the poor and assist in advising mothers as to the caring for and feeding of infants, and as to domestic sanitation generally. With such weight given to the Committee's proposal, we should have thought that it would have been carried unanimously, but several of the members fought against it, as if the introduction of a woman

Inspector was an outrage upon the community. Perhaps there was something more than prejudice behind their action. Do they fear that a woman will find out "too much"? Eventually the recommendation was carried, but action was deferred for six months. Such a "wobbling" Council is not likely to inspire much confidence.

Fighting Plague in India.

According to the *Bombay Gazette*, a somewhat novel experiment was recently tried in Bhownager, with the object of freeing the town from some of the diseases which prevail at intervals with disastrous results. One of the chief objects in view was to diminish plague, and to this end, between six and seven o'clock, every street, lane, or alley, was thoroughly fumigated with damar or sulphur. The whole town was enveloped in smoke and presented a strange appearance under the pale light of the moon. This process of simultaneous fumigation was continued for five days. It began on the 15th ult., all the houses doors, and floors being washed with well-known disinfecting solutions. All drains had been disinfected and cleansed in the same manner, and tons of dust and filth, the accumulations of years, were removed. The Darbari officials, with the aid of well-known and energetic citizens, were appointed by the Mahajab in each ward to superintend this work, and all citizens are deserving of the highest praise for their co-operation. It is fervently hoped that by these measures the health of the town will be considerably improved, and that plague and other kinds of dangerous disease may be materially lessened, if not entirely suppressed. The most noticeable fact in these operations has been the total absence of apathy or prejudice on the part of the people, and this no doubt is owing partly to personal influence of the Mahajab, and to moderation and conciliatory attitude of gentlemen in charge of operations towards the people. This latter fact marks a great improvement, for nothing has stayed the advance of health reform in India so much as the blind prejudice of the natives to anything contrary to their innate desire to be left alone in their filth and degradation.

Nursing Institutes.

One of the best features of the closing years of last century was the establishment of nursing associations in all parts of the country. The benefit they confer upon the community, and especially to the poorer members, is immeasurable, and not only do they help to prevent unnecessary suffering, but they have done much to rescue the poor from the coils of the "wise women" who have lived so long upon the credulity of their victims. Some idea of the work done may be gathered from the report presented at the annual meeting of the Birmingham District Nursing Society, which was held last week. In the year 1900 over 2500 cases were attended, and these received over 57,400 visits. In six years the operations have doubled, and yet the Committee feel they have scarcely touched the fringe of the work that should be done. Speaking at this meeting, the Lord Mayor of Birmingham urged that two or three manufacturers should combine to support a nurse for the benefit of their workpeople. That, he thought, was a very excellent thing to bring home to the Birmingham manufacturers. There were very few firms now-a-days that had not been converted into limited liability companies, but he did not see why such a work might not appeal to a board of directors equally as to a private manufacturer. It seemed to him so sensible and practical a thing that it should be done generally throughout the city. If two or three manufacturers could not afford to support a nurse, half a dozen, perhaps, in a district might combine to do so for the benefit of their workpeople, or perhaps something might be done through the sick societies that existed in connection with most large works. He could not endorse the view that manufacturers in Birmingham failed to recognise the benefit of health to their workpeople, because very many of the large manufacturers did give a good deal of attention to such matters as the sanitary condition of their establishments. We commend this suggestion to the great merchants of other towns. We know of no branch of philanthropic and social work in which so much real good is done at a small cost, as by nursing institutes, either in the town or rural districts.

Sanitary Officers at the Front.

A correspondent of the *Morning Post* has forwarded to that paper an extract from Lord Wolseley's "Soldier's Pocket-book for Field Service," which comes down very heavily upon the "Sanitary Officer in the field." The quotation tells us that the "Sanitary Officer is a creation of recent years, and as a general rule he is a very useless functionary. In the numerous campaigns where I have served with a Sanitary Officer I can conscientiously state I have never known him make any useful suggestion, whereas I have known him make many silly ones. It is not his fault, for with an army moving it is impossible to drain a town, as I have known suggested, or carry out any other great sanitary measure. There is not time for any great sanitary works, and for the ordinary cleanliness of temporary camps or bivouacs the P.M.O. (Principal Medical Officer) with each division can do all that is necessary. In future, as long as this fad continues, my recommendation is to leave him at the base, where he may find some useful occupation as a member of the Sanitary Board, which I think should have charge of all sanitary arrangements at the base." We presume that the sender of this extract thinks that it entirely discredits the contention of Sir Walter Foster and others that a properly-qualified sanitary expert should have accompanied our army to South Africa. But we do not think it does anything of the kind. We grant that Lord Wolseley has had considerable experience in active service, but neither he nor any other living general, has ever taken part in such a war as that which is at present going on in South Africa. It

may be perfectly true that when fighting is going on the sanitary expert is not required; but fighting has occupied but little time in this war, and where bullets have slain their hundreds, disease—and that preventable disease—has slain its thousands. It is on the camping grounds that the sanitary expert should have been in evidence, and by his advice, and better knowledge and quicker perception of dangerous surroundings and conditions, he might have saved many of the precious lives which have been so ruthlessly sacrificed. Every war is different, and provision should be made for every emergency. Better to have even a "faddist" with the army than lose soldiers from enteric fever by the thousand.

Queensland's New Health Commissioner.

The papers to hand from Brisbane announce the arrival in that city of Dr. B. B. Ham, who has been appointed Health Commissioner for the Colony. The irrepressible interviewer met him and tried to gather some idea as to the work Dr. Ham intends to initiate and carry out. He confessed that he was greatly impressed with the vastness of the Colony, and Brisbane itself was a much more extensive and go-ahead place than he had imagined. But Dr. Ham made it clear that he did not propose to slavishly follow the lines laid down in the British Public Health Acts. He fully realises that he has a new country to deal with, that instead of having to break through prejudices made strong by generations of bad practice and ignorance, he can commence at the very beginning and build up the nation on true hygienic principles. Thus he believes it possible to educate the people up to such a standard in regard to sanitation that they will understand and appreciate Queensland's new Health Act, which contains many provisions and terms new to the laws of the Colony. "This education," said Dr. Ham, "must tend to make a man more careful of the water he drinks, the food he eats and the air he breathes, the soil he treads on, and the house he lives in," and by this means a factor will be created which will make the sanitary administrative machinery easy in its working. We have always maintained that sanitary science knows no political party, nor is it the monopoly of any sectarian creed It is the handmaid of all true religion, and the health officer is, in the words of the present French Prime Minister, the most valuable and indispensable *collaborateur* of all or any Government. It is in this spirit that Dr. Ham is entering upon his new duties, and he has gone out armed with every appliance and method he could gather together to help in fulfilling the high ideal he has set before him. That he does not anticipate all will be smooth sailing is indicated by the closing reply to his interviewer. "I understand," he said, "that there have grown up in this Colony large industries whereby the source of public revenue has been considerably increased. And should I, in the course of my public duties, have to deal with vested rights and properties, I shall do so with careful consideration, mindful of the interests involved; but where I find danger to the public health, or gross insanitary conditions, I shall take no half-hearted measures, form no halting decision as to the means to be adopted to have these defects remedied. Pure air, pure water, pure food, pure dwellings, are texts as old as the doctrines of Moses; and yet they are the watchword of the sanitarian of to-day."

REVIEWS.

The Sanitary Inspector's Field Book, for Use in Rural Districts. Compiled by H. G. Keywood. Maldon: Richard Poole. Price, 2s. 1900.

The object of this note-book is to reduce to a minimum the inconvenience of taking notes during rain. For this purpose a number of headings are given, and these the Inspector ticks off if they apply to the premises inspected. The idea is a good one, but the book would perhaps be the better for some simplification. Indeed, so many useful additions might be made that it is a question whether or not the old style note-book is, after all, to be preferred. The note-book is applicable, the author states, to both cottage and mansion, but surely the Inspector will wish to know something more of the drainage arrangements of the latter than the items comprised in the book, namely, "gully," "sink waste," "pipes," and "where to." Then, again, "good," "bad," and "medium" may mean anything or nothing. Altogether, it appears to us the book is conducive to a superficiality of inspection which is not at all desirable, and which, in the interests of the public health, we trust is not frequent.

Public Works.

SEWERAGE.

Rochdale has obtained sanction to a loan of £8000 for the reconstruction of the workhouse drainage.

At a recent meeting of the Maxwelltown Town Council it was resolved to proceed with Mr. Carter's scheme of sewage disposal, at a cost of £14,000, subject to some modifications.

Mr. A. H. Wyrill, Borough Engineer, recently reported to the Swansea Water Committee on the proposed cost of the Brynmill sewer outlet and septic tank schemes. The total estimate was £57,200. There was an alternative scheme estimated to cost £80,000.

Last week at a special meeting of the Rotherham Town Council, the Mayor (Mr. G. Gummer, J.P.) presided, and moved the following resolution, which was agreed upon:—"That the Corporate Seal of the Corporation be affixed to a mortgage to the Public Works Loan Commissioners for £45,775 for sewage works purposes; also to an authority to the secretary of the Commissioners to deliver the certificate for £20,000, part of the said sum, to the Sheffield and Rotherham Joint Stock Banking Company."

The Atcham Authorities, through their Surveyor, Mr. J. Morris, have been making inquiry into the various methods of sewage disposal, with a view to the adoption of a scheme, and after visiting a number of sewage purification works, Mr. Morris reports that he considers the best systems are those in operation at Reigate and Oswestry. He gives the preference to Reigate for its greater simplicity, it being an oxidising bacterial system combining Candy automatic sprinklers and intermitters upon polarite beds.

The Eastry Rural District Council has, after considerable discussion, resolved to apply to the Local Government Board for a loan not exceeding £2000 for alterations in the sewage disposal works, in accordance with the plan, specification, and estimate prepared by Mr. Anson.

The Lanchester Rural District Council has declined to join the Durham Council in regard to the disposal of the Ushaw Moor drainage, because its share would amount to between £1200 and £1300, whereas the Council estimates that it could carry out the work affecting its own area for £400. The Local Government Board has written the Rural District Council, stating that it would be advisable that there should be combination between the Durham Council and the Lanchester Rural District Council for the treatment and disposal of the sewage of the whole of Ushaw Moor at one outfall rather than that independent outfall works should be provided for each part of the village.

At a special meeting of the Dumfries Town Council, Provost Glover submitted a proposal in connection with the treatment of sewage to purchase the estate of Castledykes, at the south end of the town, and to use the flower gardens there as a site for septic tanks. He stated the purchase could be effected for £7000, including the mansion-house, and he suggested that this might one day be used as a museum. No pumping would be required at the works, and the whole scheme would cost about £17,000, or over £40,000 less than Mr. Carter's. The proposal was adopted, and a committee was appointed, with power to submit it to Lord Balfour after consultation with Mr. Carter. By this scheme an acre and a-quarter will be used for contact beds, instead of some twelve acres which Mr. Carter's scheme provided for.

Upon a report from Mr. Willcox to the Hanley Town Council on the suggested bacterial treatment of a portion of the sewage at the Hanley sewage works, the Sewage Sub-committee recommended that a new tank adjoining tank No. 5, but at 3ft. higher level, with a capacity of 500,000 gallons, should be provided at the works; that the two bacteria filters, having a total area of 2000 square yards, should be proceeded with; that Mr. Willcox should be instructed to provide a scheme for laying out the low-level land, with the view of meeting the requirements of the Local Government Board as to final treatment of the effluent before discharging it into the river; and that the sewage from the east side of Northwood should be treated on the bacteria system by means of small works at Sandy Finney Field. The recommendations were adopted.

The report of the City Engineer to the Sewerage and Irrigation Committee was presented to the Norwich Town Council last week. The sewerage works as contemplated are finished, and the estimate of five years ago has only been exceeded by something like 1 per cent. Anyone who has at all studied the matter will be aware that to come so near on five years' work, in such a field, and with prices continually going up, is no ordinary feat. Moreover, the sewers are working not only efficiently but economically; many of the old insanitary conditions have been got rid of by simple methods of re-formation, and the health of the city has considerably improved since the work reached its concluding stages. When water carriage for sewerage is universally adopted, and the middens swept away for good and all, Norwich will be able to be advertised as a health centre, and plans will be laid to recoup the ratepayers for all their outlay on sanitary works. The task has been a costly one. The £153,000 that was the amount of Mr. Collins' estimate is by no means the only item in the stupendous account which has been running ever since 1868.

The Local Government Board inquiry being held at Stockport into the application of the Corporation for an extension of the borough boundaries, was resumed on Wednesday in last week, that being the sixth day. Mr. W. Spinks, civil engineer, who prepared the plans of the Bredbury sewage works, said he had selected a site at the Rifle Range for the final treatment of the sewage. At the present time plans for the completion of the works were under consideration, and in his opinion Bredbury could deal satisfactorily with the sewage of Brinnington. If Stockport were to change its existing system of sewage treatment to the bacterial system the cost would be at least £100,000.

A Local Government Board inquiry was held at Coventry last week, into the proposal of the City Corporation to borrow £32,962 for sewerage works and surface-water drainage, including the construction of works in the parishes of Foleshill and St. Michael's Without, and £1150 for the purchase of land for street improvements. The City Engineer (Mr. J. E. Swindlehurst) went over the plans of the proposed sewerage system with the Commissioner, and explained fully about the details of the scheme to him. Answering questions put by Colonel Slacke, the Engineer said that the present means of sewage disposal pumping on the new sewage farm would be sufficient for the increase. They had at the present time a flow of about 3,000,000 gallons per diem, of which probably 1,000,000 was subsoil water. The total population estimated for was 80,000. That was the basis of the estimate, but the works would take a considerably larger amount than that. They had not estimated what the population would be in thirty years. The works were capable of extension on the present site, and the pumping capacity was 12,000,000 gallons per diem. The works were practically completed, with the exception of one engine, and pumping on to the farm would be begun last week.

WATER.

The Darlington Town Council contemplates an extension of the borough waterworks at a cost of £22.000.

At the West Gloucester Water Company's works at Frampton Cotterell, the formal opening of a new engine-house and pumping engine recently took place, in the presence of several directors, shareholders, and other gentlemen interested in the progress of the company.

The result of the poll on the proposal of the Margate Corporation to expend £150,000 in an effort to secure a water supply from the village of Wingham has resulted thus: For the Bill, 1443; against, 1807; majority against, 364. The proposal to increase the membership of the Town Council is rejected along with the water clauses of the Bill.

The syndicate which carried out successfully the water scheme for Wetherby has offered to undertake a new water scheme for Thorne. Hitherto the people of Thorne have been dependent on the canal and private wells for their water supply, and in spite of the order of the West Riding County Council that this unsatisfactory arrangement should cease, they are quite content to be as they were. In fact, bitter hostility is shown by the ratepayers to any alteration. The rates are already high, and any additional burden would fall heavily on the farm labourers, who form a large portion of the population. This being so, the offer of the syndicate may be very acceptable, provided the sanction of the County Council is obtained. The undertaking will no doubt prove an expensive one, but it is evident that a good supply of water can be obtained, and in course of time the scheme will assuredly develop into a good paying concern.

At the last meeting of the Bootle Rural Council the clerk reported that the Sub-committee on the Barrow Water Bill had met the Committee of the Ulverston Rural Council, and they had agreed to jointly file a petition against it. The cost of the petition would fall on the two districts according to the rateable value.

The March Urban District Council has decided to join with the Corporation of Wisbech in presenting a petition against the Bill now being promoted in Parliament by the Wisbech Waterworks Company. At Wisbech a poll of the inhabitants is to be taken. It was stated by a Wisbech contemporary that the real question behind the opposition to the Bill is the desire to obtain powers to purchase the undertaking.

At the last meeting of the Louth Town Council, the Highways Committee reported in favour of the purchase of the Louth Waterworks, and advised that £15,100 be offered for the undertaking. Dr. Best moved that a special meeting of the Corporation be held to consider correspondence from the Waterworks Company. He said the sum named was a startling amount. It was decided to discuss the question by a committee of the whole Council.

An ordinary general meeting of shareholders in the Felixstowe and Walton Waterworks Company was held last week. In their report, the directors stated that the dividend and interest account showed a balance of £1787 13s. 1d., and that they had pleasure in recommending the payment of a dividend of £5 5s. per cent. per annum on the original share capital, and £4 18s. on the additional share capital. The shareholders were also informed that the new tower, service tank, and cottages at Trimley will probably be completed before the summer season.

The Water Committee of the Liverpool City Council met last week. Mr. Wm. Houlding, the new member of the Committee, attended for the first time, and the Chairman, on behalf of the Committee, said they were very glad to see the new member of the Committee present, and he hoped he would be of great assistance to them. The engineer's report stated that the total quantity of water supplied, both within and outside the compulsory limits, for the week ending February 9th, was 182,848,000 gallons, as against 192,371,000 for the same period in 1900. For the week ending February 16th there were 189,311,000 gallons, as against 234,772,000 for the corresponding week last year.

The question of the water supply to Hadley was discussed at a meeting of the Wellington Rural District Council recently. The Clerk read communications from the East Salop Water Company expressing willingness to extend their scheme of supplying Oakengates with water to Hadley. Mr. M. H. Bailey said the Urban Council, in whose water area Hadley was, were no nearer supplying water to that place than twenty years ago. The East Shropshire Company were prepared to spend £70,000 on works, while the minimum cost of the scheme proposed by the County Council would reach £170,000. It was resolved to consider the question again after it had been brought before a special meeting of the Urban Council convened for that purpose.

LIGHTING.

Additional works in connection with the supply of electrical energy by the Liverpool Corporation are the subject of a proposed loan of £300,000.

There is to be moved at the next Gravesend Town Council meeting a motion to rescind the resolution passed to adopt the electric lighting scheme.

The result of the year's working of the Taunton electrical undertaking is a net profit of £706. The prices to private customers and places of worship are to be reduced to 4d. and 5d. respectively.

The South Metropolitan Gas Company contemplates a reduction in the price of gas of not less than 2d. per 1000 cubic feet from June.

The Committee of the Gillingham District Council has decided to recommend the Council to purchase the electric lighting works in that town at a valuation.

Following the example set by Shoreditch, by Poplar, and more recently by Fulham, the new borough of Hackney will, we understand, soon be in possession of its own electric light.

The fifth annual report of the Windsor Electrical Installation Company shows a net profit for the year of £4372 11s. 11d., and this would have been considerably increased but for the high price of coal.

The report of the directors of the Ascot District Gas Company for the half-year ended December 31st, states that, after providing for every charge against the half-year's working, there remains a balance of £2155 at the credit of profit and loss account, out of which the directors recommend that a dividend at the rate of 5 per cent. per annum be paid on the share capital, £967 being carried forward.

Last week the new gasholder at Stirling, which has been in process of construction for some months past, was formally inaugurated in presence of the directors and a few friends. Mr. Robert H. Donald, of the firm of Hanna, Donald, and Wilson, engineers, Paisley, on behalf of the contractors, presented Mr. James Johnston, chairman of the company, with a gold key, suitably inscribed, as a memento of the occasion.

Including the amount brought forward, the balance of revenue for the past year from the Brompton and Kensington Electricity Supply Company is £21,836. A dividend on the ordinary shares for the half-year is recommended at the rate of 7 per cent. per annum, making 6 per cent. for the year. The sum of £6000 is allowed for depreciation, £3000 placed to renewals expense account, and £488 carried forward. The directors propose to issue 8000 preference and 330 ordinary shares, in order to reduce the existing debenture stock.

After a year or two of hard work, in the course of which many unexpected difficulties have had to be surmounted, the scheme of the St. Anne's Council for lighting the town with electricity is now nearing its completion, and within a very few weeks from now the Council hope to have the works in full swing. The generating station, which is situated north of the gasworks, has been erected by Messrs. Moore Brothers, and is a substantial building of red brick, with freestone facings, and contains boiler-house, engine-room, accumulator-room, test-room, and workshop, store-room, and engineer's office. The boiler-house contains two multitubular boilers (by Stephenson and Co., Preston), each of 250 horse-power, and working at a pressure of 140 lb. per square inch.

Following hard upon the enterprise of the borough of Fulham, the London County Council inaugurated last Saturday its long-talked-of scheme for the illumination of the Victoria Embankment and Westminster Bridge by electricity. Mr. W. H. Dickinson, chairman of the Council, presided, and his little daughter performed the formality of switching the current to some of the parapet lamps of the Embankment, the little ceremony taking place at the generating station, which has been built beside the Charing-cross Station of the District Railway. The undertaking has been carried out by the Highways Committee at a cost of about £25,000, and will certainly help to remove the dreary and neglected appearance that has hitherto characterised the fine roadway from Westminster to Blackfriars after dark, while possibly, too, it may help to relieve the congestion of traffic in the Strand and Fleet-street.

Fulham's new electric lighting system, which has been installed at a cost of £130,000, was formally inaugurated last Thursday afternoon. In the course of the proceedings the consulting engineer mentioned that there was nothing in the plant which had not been manufactured in Great Britain.

GENERAL.

The Littlehampton Urban Council is considering tenders for paving the extended portion of the esplanade.

By order of the Pudsey Town Council, all houses in which fatal cases of consumption occur are to be thoroughly disinfected.

The Worcestershire County Council has agreed to apply to the Local Government Board for sanction to a loan of an additional £2000 for the Bromsgrove, Droitwich, and Redditch Hospital, making a total of £12,000.

During the month of January Mr. Kenneth Cameron, Sanitary Inspector, Aberdeen, seized and destroyed as unfit for human food 9870 lb. of beef, 132 lb. of mutton, 386 lb. of pork, 74 lb. of veal, 1176 lb. of offal, and 140 lb. of fish.

The electric tramway connecting Bournemouth with Poole is now practically completed, and will be inspected shortly by the Board of Trade. The construction of tramways within the borough of Bournemouth will shortly be commenced by the Corporation.

The Edmonton Board of Guardians has decided to carry out works at the Edmonton House with reference to alterations to the boiler-house, new chimney shaft, new 100 horse-power boiler, lift for new infirmary, and tanks, &c., for softening water, the cost of which is estimated at about £7000.

Dr. J. Wright Mason, Medical Officer of Health, Hull, has formally certified that no case or death from plague has taken place in the city and port since the recovery of the last patient who was discharged from the hospital on Monday, 11th instant, and that the steamer Friary, on which the outbreak of plague occurred, was allowed to leave the port on the 10th instant, after having been disinfected under his direction and to his satisfaction.

Besides the Tottenham scheme referred to on another page, the Housing Committee of the London County Council on Tuesday gave several particulars of the work it has in hand. On the Totterdown estate, Tooting, it is proposed to accommodate 8532 persons in 1244 cottages on the 38¾ acres. Four of the roads will be 45ft. wide, and these will be lined with plane trees. On the Reid's Brewery site, Clerkenwell, five-storey block dwellings all round will be erected, except on the Gray's Inn-road frontage, where the existing buildings will remain for the present. The main interior of the site will be occupied by five five-storey transverse blocks of dwellings, divided by yards and gardens. Another block of five-storey dwellings will occur in the narrow end of the site next Gray's Inn-road, and the remainder of the area will be laid out as a playground and garden. Exclusive of shops, accommodation will be provided for 2614 persons. On the Duke's-court, Drury-lane, site, 610 persons are to be housed in three blocks of five-storey dwellings. A noteworthy paragraph in the report reads:—"We have to report that during the year ended December 31st, 1900, weekly rents amounting to £93 16s. 9d., and charges for use and occupation amounting to £96 12s. 11d., have become irrecoverable in respect of the Council's dwellings. This represents a percentage of only ·50 on the total gross rents receivable during the year, viz., £37,451. Such a result appears to us to be highly satisfactory."

On Tuesday last the Leicester Town Council brought forward a proposal to the effect that "£50 shall be spent in providing, stocking, and distributing flower boxes to be placed in first-floor windows in some of the poorer neighbourhoods of the town."

After being closed for four weeks in consequence of an epidemic of measles, the schools under the Bo'ness and Carriden School Board have just been reopened, but a number of them have had to be closed again, there being no abatement of the prevalence of the disease.

Owing to the small-pox epidemic, Glasgow medical men are very busy with cases of re-vaccination, a fee of 1s. 6d. being paid by the authorities for all those who are unwilling or unable to pay the fee. Two hundred and forty thousand operations have taken place, but as the city contains nearly 600,000 adults, a special appeal has been made by the Town Council to those who have not yet been re-vaccinated.

Steady prosperity still attends the tramways of the London County Council. The traffic receipts during the week ended February 16th, 1901, amounted to £6946, including £126 from the all-night services, while the receipts for the corresponding week in 1900 amounted to £6759. The total receipts for the year, up to the same date, amounted to £48,908, while those for the corresponding period in 1900 were £48,507.

A street-cleaning machine, says *Indian Engineering*, has recently been tested in New York, which contains many features of interest. It is drawn by a couple of horses, and performs all the functions of a street-cleaning gang, except scraping the roadway with the rubber squeegees which are used on asphalt. A revolving broom sweeps the dirt to a conveyor, lifting it into a covered bin. Just in front of the broom there is a horizontal pipe through which jets of water are sprayed on the street so as to prevent dust. The dirt collected in the bin is distributed uniformly through it by means of a scraper, and when the bin is filled it can be discharged into a cart or on to the ground in a heap by letting down a door and scraping the contents out by a simple form of conveyor. The water is carried in a tank below the bin.

The subject of lady Corporation Inspectors was raised by Alderman Ruddin at the last meeting of the Liverpool Health Committee, who asked what they were doing. He referred to a particularly shocking case of child neglect and domestic squalor reported in the papers, and said he understood the female Inspectors were intended to visit such places and bring their existence to the knowledge of the Authorities. He thought clergymen connected with the different denominations might be asked to report such cases. Alderman Roberts said he thought, when they were appointed, those ladies would go into the houses of the poor, and that the city would get rid of all this squalor, crime, and child neglect. The Chairman reminded the Committee that there were but eight female Inspectors altogether. They went about the lower parts of the city, visiting the homes of the poor, and instructing them in domestic matters and the care of children. They reported on their work from day to day to Dr. Hope, the Medical Officer. It was very important but somewhat difficult work, and the ladies were working very hard. At first the poor people were inclined to resent their visits, but now, thanks to tact and kindness, they were generally well received. Alderman Roberts said something more ought to be done in such cases as Alderman Ruddin mentioned. The Chairman said the lady Inspectors were doing a good work, and their efforts had already had a good effect upon the health of the poorer localities. A member remarked that the cost of the lady Inspectors to the city was about £16 a week.

Turkish baths are to be provided by the Carlisle City Council at the public baths.

The Chard Union, Somerset, having appointed a licensed victualler one of their Sanitary Inspectors, have been informed by the Local Government Board that he cannot hold the office. The South Somerset Licensed Victuallers' Association are going to lay the facts before Parliament. We sincerely trust they will, for nothing is more to be desired than that these "jobs" should be made public. It is time that a stop was put to admitting such individuals to the public health service.

As the Rangoon Government proposes taking over the Rangoon Hospital, the reclamation works, and the new water scheme, it is not quite clear why Rangoon requires the services of a highly-paid municipal engineer. A saving of some thousands of rupees per mensem might easily be effected in the municipal works establishment now that Government Public Works Department officers are to do the principal work. The town roads will, of course, have to be kept in repair, but a highly-paid engineer is not wanted for that.

The low death-rate of Ilford, which has attracted attention of late years by reason of its rapid growth, was stated by the Medical Officer of Health to be 8·33 in the last report, while the birth-rate for a corresponding period averaged 36·33 per thousand. No wonder the numerous houses which are in constant course of erection so soon become tenanted. We know that environment has something to do with the death-rate, and a study of the returns raises the question as to whether it does not affect the birth-rate as well.

It is reported that the Special Committee of the Leicester Corporation has commissioned Mr. Manville, of London, to mature a scheme for applying electric traction to the whole of the Leicester tramways, as well as to a large extension of the present system, which has now been sanctioned. It is roughly estimated that the total expenditure on the acquisition of the present lines, and the completion of the new ones, will considerably exceed half a million sterling, if not reach three-quarters. The Committee had almost unanimously recommended the adoption of the overhead trolley system, but after the startling experience at Liverpool there is a strong revolution in feeling, and a growing determination to declare for the conduit system, though it must entail a large addition to the initial cost. The report of Mr. Manville is awaited with a good deal of interest.

A Local Government Board inquiry was held at Southport last week into an application by the Southport Corporation to acquire by compulsion about ten acres of land in the parish of Scarisbrick for the erection of an infectious diseases hospital. There was considerable opposition from Scarisbrick. The Town Clerk, Mr. J. E. Jarratt, who conducted the case for the Corporation, in opening, contended that a new site was absolutely necessary, and that, apart from the extravagant and prohibitive costs of a site within the borough, there would be tremendous opposition to such a site. The circumstances also in regard to the tenure of the land in the borough were exceptional, nearly the whole of it, with insignificant exceptions, being leasehold. The Sanitary Committee had been unable to find a suitable plot for a hospital within the borough, every unoccupied plot having been inspected. The owners of the land within and without the borough had refused to sell land to the Corporation by agreement, and they had to resort to compulsory powers. The site which had been chosen at Scarisbrick, and which was 1¾ miles from the boundary of the borough, was from a matter of necessity and desirability the best possible site for the purpose. There would be no danger to the neighbourhood, and no damage done to the landlord beyond what money could compensate.

At a meeting of the Hanley Town Council last week, the Medical Officer of Health reported that owing to the continued prevalence of diphtheria he had sent to the various schools a letter, in which he stated that in view of the likelihood that the disease was spread amongst children by the use of the same slates and slate pencils, which were frequently sucked by them, he thought it advisable that all the slates and pencils should be placed in a disinfecting liquid every night, and then washed each morning before being given out. He recommended the Corporation to supply the disinfectant. There were eleven cases of typhoid fever notified during January, and seven cases up to the 6th February. These cases were principally amongst children going to school, and several of them had been in the habit of eating ice-creams or ice-cream wafers. He inspected one of the localities where ice-cream was manufactured, and found it in a very dirty condition. Notice had been sent to limewash and cleanse the premises, but they had no power to prohibit the manufacture, unfortunately. He thought it would be advisable to take some samples of ice-cream and have them analysed bacteriologically.

PERSONAL.

Dr. B. H. Kingsford has been appointed Medical Officer and Public Vaccinator for Woking.

Dr. C. J. Ellis has been appointed Medical Officer and Public Vaccinator for No. 3 district of Battersea.

Mr. W. J. Coleman has been appointed Inspector of Nuisances for the rural district of Mutford and Lothlingland.

Dr. B. Kingsbury has been appointed Medical Officer and Public Vaccinator for the Woking district of Guildford.

Mr. G. F. Metzger, of Bath, has been appointed Chief Electrical Engineer for Manchester, at a salary of £800 per annum.

Dr. J. Fletcher Little has been reappointed Medical Officer of Health for Harrow, at a salary of £120 per annum.

The salary of Mr. O. M. Jonas, electrical engineer to the Dewsbury Corporation, has been advanced from £250 to £350 per annum.

Mr. C. F. Parkinson, Morecambe, has been appointed Electrical Engineer to the borough of Paisley at a salary of £250, with a free house.

Mr. E. Cross, the works engineer at the Aberdeen Corporation Electricity Works, has been appointed Electrical Engineer to the Rotherham Corporation.

Mr. Albert Ford, a native of Maldon, has been reappointed Manager of the gasworks at Singapore at a salary of £1000 per annum. He has held the position for four years.

Dr. Alex. Robb, of Hamilton, has been appointed Medical Officer of Health for the burgh of Paisley, in room of Dr. Robertson, who leaves for Leith. The salary will be £400 per annum.

The Bengal Government has confirmed the appointment of Mr. Alexander Hale, M. Inst. S.E., as Superintendent of the sanitary department of the Howrah Municipality, Calcutta. Mr. Hale, who is a Londoner, and an Associate of the Sanitary Institute, received his training as a Sanitary Inspector and Engineer under Mr. Moss Flower, C.E., of Bristol, and he was for many years chief of the sanitary department at Simla, the summer headquarters of the Viceroy of India. His frequent visits to the old country on leave have enabled him to keep his sanitary knowledge up to date.

Dr. Vincent O'Reilly has been appointed Medical Officer of Health and Public Vaccinator for Skelmersdale, in room of Dr. Morris.

Mr. C. W. Thompson, of Penrath, has been appointed Surveyor and Inspector of Nuisances for Ripley at a salary of £150 per annum.

Mr. F. C. Everett, District Surveyor, Liverpool, has been appointed an engineer on the staff of Mr. C. F. Wike, the City Surveyor of Sheffield.

Dr. P. Caldwell Smith has been appointed Medical Officer of Health for the borough of Wandsworth, at a salary of £800, rising to £1000 per annum.

The Grays Urban District Council has unanimously agreed to increase the salary of Mr. Arthur C. James, Surveyor to the Council, from £250 to £300 per annum.

Miss Florence Mary Nicholas, of Eltham, and Miss Mona W. Richardson, of Battersea, were appointed women Sanitary Inspectors for Southwark at the last meeting of the Borough Council. The commencing salary in each case is £110 per annum, rising to £160.

Mr. Neil J. Peters, of the Waterworks Engineer's Department of the Southampton Corporation, has been appointed Assistant Waterworks Engineer to the Cardiff Corporation. The commencing salary is £165 per annum, rising by annual increments of £20 to a maximum of £200.

The Hoylake and West Kirby District Council has resolved to permit Mr. Foster to resign his position as Surveyor and Inspector of Nuisances to the Council, and to appoint him as Engineer for the works authorised by the Improvement Act of 1900, at a remuneration of £1800, spread over three years, in the hope that at the expiration of that period he will be able to again take up the position of Surveyor to the Council, the present assistant being made Surveyor in the meantime.

At the last meeting of the Camberwell Borough Council, Mr. R. H. Lord, who has served the Vestry continuously for over twenty-three years, wrote resigning his position as accountant, and requesting the Council to grant him his superannuation according to the London Government Act. The resignation was accepted, and Mr. Lord was reappointed an officer of the Council temporarily pending the decision as to his compensation. It was decided that the future salary of the chief accountant should be £500 per annum.

LAW CASES.

Adulteration of Barley.

At Inverness on February 21st, before Sheriff Grant, Messrs. Anderson and Co., grocers, were charged at the instance of Mr. Alexander Knowles, Sanitary Inspector, with a contravention of Section 6 of the Food and Drugs Act, 1875, in having sold to the prosecutor 2 lb. of barley which was not of the nature, substance, and quality demanded, in respect that the sample purchased was found on analysis to possess a coating of powder to the extent of at least two per cent., and 40 per cent. of this powder being of the nature of fine white earthy matter or clay. The analyst's certificate added that the mineral addition had evidently been made for the purpose of improving the appearance of the barley. Mr. Herbert C. Boyd, solicitor, appeared for the prosecution, and Mr. C. O. Morris, solicitor, for the defence. Evidence was led, in the course of which it was elicited that the finer kind of barley, known as pearl barley, is distinguished from the commoner or ordinary pot barley by its fine white colour—a fact which, it was contended for the prosecution, was sufficient to account for the adulteration complained of. For the defence it was argued that the earthy matter might have been accumulated in the course of transit or manipulation. The Sheriff, however, found the charge proved, but as he was satisfied that the accused was not personally to blame, and as the case was of the nature of a test case, no previous case of barley adulteration being known to have occurred, he modified the penalty to £1, with £2 of costs.

A Deposit of Manure.

An action was recently brought in the Sheriff Court of Peeblesshire, under the Public Health (Scotland) Act, 1897, to have Alexander Roxburgh, farmer, interdicted from depositing any offensive matter or refuse within fifty yards of Thornielee Railway Station-house for a longer period than four days. Sheriff Pitman has granted interdict, and found the respondent liable in the sum of three guineas as modified expenses. In an exhaustive judgment he states that the respondent has been in the habit of receiving from two to four truckloads of Galashiels town refuse a day at Thornielee Station for use on his farm. In December a quantity of this refuse was deposited by him in a field adjoining the station and a public road. On 17th December the place was visited by Dr. Brock, the County Medical Officer, accompanied by the County Sanitary Inspector, and on the same day Dr. Brock reported to the Local Authority, in consequence of which the respondent was given notice to remove the offensive matter within forty-eight hours. It was proved that the manure was dangerous to health if deposited near a dwelling-house or a road, as was done in this case. Since May last the stationmaster's daughter had contracted a lung complaint, and though it was not proved that this was caused by the presence of the manure in the neighbourhood, it was impossible to provide her with the fresh air which had been prescribed, on account of the doctor having had to order the windows of the house to be closed in consequence of the ill-effects likely to follow from the effluvium of the manure. This was so strong that Dr. Brock's clothes smelt of it on the day following his inspection, though he had not been in direct contact with the manure. The deposit on the field was left for a longer period than was necessary for the purposes of agriculture, and the respondent's only excuse was that his ploughs were at the top of the hill, and it would have put out his arrangements to bring them down at that time. The Sheriff accordingly interdicted him from repeating the nuisance.

Alleged Insanitary Ship.

At Cardiff Police-court, before the Stipendiary, a case was heard in which Robert Forrester claimed £5 12s. from Robert Morrison.

Mr. Forsdike, instructed by the Sailors' and Firemen's Union, appeared for the plaintiff, and Mr. Ingledew for the defendant.

Plaintiff is a fireman, and was on February 7th engaged upon the s.s. Benvenue, belonging to defendant. It sailed from Cardiff on February 8th. Plaintiff and three others were engaged at the last moment, and when they got on board and were on the point of sailing they made their way to the fo'castle, and found it in a filthy condition, and they were deprived of the accommodation which the Act provided for them. Plaintiff and the others complained to the captain, who told them to go about their work. He said he would not until the fo'castle was put into a sanitary condition. When the ship arrived off Barry the captain brought the police on board, and plaintiff and his companions were taken before the Barry magistrates on a charge of refusing duty under the Merchant Shipping Act. The defendants on that occasion urged that the ship was in an unsanitary condition, and it was a fact that the

donkeyman was taken away by the Sanitary Authorities suffering from small-pox in its initial stages. After their discharge the men were vaccinated.

The STIPENDIARY asked if they claimed for the time during which they were recovering from the vaccination. Mr. Forsdike said that it was so. The Stipendiary said that he thought that too remote. The words of the Act were "receive any hurt or injury," and surely that referred to some bodily injury received in the course of employment. Mr. Forsdike urged that the fact that they had to be inoculated was due to the insanitary condition of the ship, and the Sanitary Authorities had compelled them to be vaccinated. Mr. Forsdike urged that a competent Court had decided that the men were justified in leaving work. Mr. Ingledew disputed the facts as set forth by Mr. Forsdike, and said that he was in a position to show that the men knew nothing about the small-pox until they were in the Barry police-station. The men were not discharged, for they went away of their own accord. Complainant was called, and admitted in his evidence that he said he would not work unless the captain took the ship into Barry.

The STIPENDIARY said that that finished the case. If the men started on board ship and dictated to the captain, all would be confusion. It was not for seamen to adjudicate if the ship were in an insanitary state, or even if it were unseaworthy. If the ship was in an insanitary state, how was it that it escaped the vigilance of the Sanitary Authorities? Port Sanitary Inspector Jenkins gave evidence to the effect that the ship was in a sanitary condition. Mr. Ingledew, in the interests of the owners, pointed out that the case of small-pox could not have been taken on board, since the period of incubation was twelve days, and the men were only on the ship two hours.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2097.—FRIED-FISH SHOPS: BYE-LAWS AS TO.—"W. H. C." writes:—"My Committee are desirous of adopting a code of bye-laws for the regulation of fried-fish shops. I have an idea that such bye-laws are in force in some towns, but cannot find where. Could you or any of your readers give me information on the subject?"

Answer.—There is some doubt as to whether an urban Authority are enabled to adopt bye-laws to regulate the trade of a fried-fish dealer. It is true that Sec. 113 enables an urban Authority to make bye-laws with respect to *any* offensive trades; but, as interpreted by the Local Government Board, it appears that to bring any trade not specifically mentioned in Sec. 112 within the scope of Sec. 113, it must be shown to be *ejusdem generis* with those specified in Sec. 112, to the extent at least of involving "the collection of substances which, without anything done to them, must be, or by progress of time must necessarily become, a nuisance to the neighbourhood," and to be actually carried on in such a manner as to be noxious or offensive. Bye-laws under Sec. 113 have been allowed with respect to the trades of a dealer in rags and bones, a fish curer, and a dealer in fish offal. The Local Authority might, however, ask the Local Government Board if they are now prepared to confirm bye-laws with respect to fried-fish shops.

2098.—INSUFFICIENT WATER-CLOSETS: POWERS OF LOCAL AUTHORITY. — "Inspector" writes:—"In this urban district notices have been served upon owners under Sec. 36 of the Public Health Act, 1875, to provide sufficient water-closets, and for that purpose to provide cisterns and flushing apparatus to same. Will you kindly advise:—(1) Whether, on the owner's default, it is imperative that the Local Authority do the work? (2) Whether the Local Authority can proceed under any other section of the Act, and compel the owner to do the work?"

Answer.—(1) The Local Authority are not bound to proceed with the work on the owner's default. The proceeding is permissive. They may or may not do the work, as they deem fit. (2) The Authority may as an alternative proceed under Secs. 91 to 96 of the Act of 1875, but it will be necessary for them to proceed against the owners before the magistrates, and to satisfy the latter that a nuisance exists, owing to the absence of cisterns, &c. If the Public Health Acts Amendment Act, 1890, is in force in the district the Local Authority may adopt bye-laws under Sec. 23 of that Act with respect to the keeping of water-closets supplied with sufficient water for flushing, such bye-laws applying to existing buildings.

2099.—BACKYARDS IN AN OFFENSIVE CONDITION: BYE-LAWS AS TO.—"A. S. I." writes:—"In my district there is a serious nuisance committed on the surface of backyards by the throwing out of objectionable matter for fowls, and which is not cleared away. Could you inform me of any towns where printed notices have been issued to stop the practice, or where notices have been issued advising the burning of refuse instead of depositing it in the ashpit?"

Answer.—We are unable to give the names of any towns where such notices as those referred to have been issued. Perhaps some of our correspondents will be able to oblige with the information, and if they will communicate with us it will be appreciated. We may point out that the Local Authority may adopt bye-laws enforcing the paving of yards at the rear of houses, such bye-laws to apply both to new and old houses. See Sec. 23 of the Public Health Acts Amendment Act, 1890, and Handford and Mackenzie "Model Bye-laws," price 25s.

2100.—REFUSE DESTRUCTORS: FAILURES OF.—"S. A." writes: "I should be much obliged if you could inform me the names of any towns in England where destructors have been erected, and which have turned out a failure or not satisfactory?"

Answer.—We are unable to oblige our correspondent. Perhaps some of our readers may be able to send us information which will be useful to him. We may observe that some of the earlier forms of refuse destructors, as might be expected, were not free from defects, but so many improvements have been introduced in the construction of the furnaces that objections to refuse destructors on the grounds of their being likely to cause a nuisance are more sentimental than real. The querist might obtain Maxwell's excellent book on "Removal and Disposal of Town Refuse," price 15s., which is the best book obtainable on the subject of refuse destructors. He might also communicate with some of the manufacturers of refuse destructors who advertise in our pages.

2101.—CANNED FOODS: METHOD OF DETECTING AGE REQUIRED.—"T. G. W." writes:—"I should be obliged if you could inform me whether there is a mode of distinguishing fresh tinned foods from tinned foods such as that from ships' stores, which may be aged. I fancy I saw in THE SANITARY RECORD some years ago that where the tins or cans from old ships' stores had been cleaned and re-coloured, you could see the second piercing. In your issue of August 13th, 1897, Dr. John F. J. Sykes refers to the subject, and Dr. John Brown read a paper on 'Poisoning by Canned Foods,' which appeared in THE RECORD Supplement of October 29th, 1897. Neither of the authors, however, gives an indication as to how to distinguish ships' old stores from newly tinned foods."

Answer.—We regret we are unable to give the required information. We shall be pleased if any of our correspondents will write us if they can supply any information which will be helpful. As Dr. Sykes pointed out in 1897, "much of the tinned foods in the cheaper markets are derived from old ships' stores. A ship upon sailing lays in certain stores of tinned foods. It often happens these are not touched on the voyage, and they may go another voyage or not, but ultimately they are sold as old stores. The tins are then cleansed, re-coloured or re-varnished, and re-labelled with clean, fresh labels, and re-sold. Considerable quantities must find their way into the London markets, and be retailed in poor neighbourhoods." If there is any means of detecting this fraud, which is also the cause of much sickness among those who buy such tinned foods, we should be most willing to expose it.

2102.—BIOLOGICAL FILTERS: COMPLAINTS AS TO OFFENSIVE SMELLS. — "Engineer" writes:—"I enclose plans showing a sewage disposal scheme recently put in by me at a country school. There are complaints that the filters, which have been working twelve weeks, give off a very disagreeable smell, noticed by passers-by in the road some 20ft. away. The number of persons in the school is about fifty. The town's water supply is laid on. There are only four water-closets. Earth-closets are used by about thirty of the boys, so that the bulk of the sewage consists of waste-water from the bath, lavatory, sinks, and wash-house. The filters are worked alternately every twelve hours. This is the first I have carried out on this system. My own opinion is that there is too great a proportion of comparatively clean water, namely, from the shower and other baths used by the boys after football, &c. Will you kindly say if you know of any similar installation, and whether there is the same complaint or smell?"

Answer.—The odour complained of arises, we think it will be found, from the trapped detritus tank where the sewage under-

THE STUDENT'S GUIDE to SUCCESS

IN SANITARY INSPECTORS' EXAMINATIONS.

By MATTHEW CHAPMAN, Sanitary Inspector, Grimsby.

This little work conveys in a compact and concise form a wealth of useful information to the student. It not only gives model questions, but explains the best mode of answering, and when necessary, of illustrating them. As a supplementary volume to the standard text-books, such as Reid's and Taylor's, it will be found invaluable, as it shows at a glance how to put the knowledge gained from these works into answers suitable for examiners.

ALTHOUGH NEWLY PUBLISHED, THE DEMAND FOR THIS WORK IS ALREADY CONSIDERABLE.

THE SANITARY PUBLISHING CO., LTD.,

5, FETTER LANE, LONDON, E.C.

goes decomposition. The odour, however, is generally very transitory, and can only be recognised within a small radius. Where such tanks are placed near highways or dwellings, to obviate complaints of nuisance the traps should be dispensed with, when the formation of scum will be prevented and offensiveness obviated. Or the tank may be dispensed with altogether, and the fresh sewage run directly upon the beds.

2103.—Housing of Working Classes: Railway Companies and Demolition.—"R. A." writes:—"Are railway companies under any obligation to provide dwellings for families displaced where extensions of their systems are about to be made? If so, kindly state the Act in force."

Answer.—No. There is no such obligation imposed upon them by any general Act.

2104.—Proceedings for Recovery of Expenses may be taken in County-court or before Magistrates.—"J. S." writes:—"Where expenses are incurred by a Local Authority under Sec. 41 of the Act of 1875, and are to be recovered in a summary manner, should such expenses be recovered in the County-court, as by Sec. 261, or before justices, as by Sec. 251, or may either course be adopted?"

Answer.—The Local Authority may at their option institute proceedings for the recovery of demands below £50, which they are empowered to recover in a summary manner in the County-court, or before a court of summary jurisdiction. They have absolute discretion.

2105.—Sewage Scheme, Clerk of Works: Parochial Committee have no Power of Appointment.—"Enquirer" writes:—"Has a Rural District Council power to appoint any person of experience as Clerk of Works, paying him a nominal salary, although he may not devote his whole time to it? May he be one that is an assistant in the engineer's office? After the Rural District Council have appointed him, can any other Committee raise any objection to his appointment and get it revoked?"

Answer.—A Parochial Committee has no power to appoint any officer in connection with the sewerage scheme. The appointment of such and the revocation thereof rests entirely with the Rural District Council. Unless, therefore, the Rural District Council revokes the appointment, the officer cannot be removed. The Rural District Council may appoint any person it chooses.

2106.—Architecture and Building Construction: How to Learn.—"R. W." writes:—"I have recently passed the examination for Inspectors of Nuisances, and now want to acquire some knowledge of architecture. What is the best way to acquire this? Does the Society of Architects hold examinations, and do they allow anyone to sit for the examination, and what books do you recommend?"

Answer.—The querist is advised to join a science and art class in building construction in connection with some technical classes. Such classes are held in the evening. After he has passed the first and second stages in the subject he will then be able to determine whether he is likely to succeed, or has an inclination to further pursue the study. Neither the subject of building construction nor architecture can be acquired without the aid of a teacher or an architect. For the examination referred to it is necessary that the candidate should have served his time with an architect.

2107.—Piggeries: Urban Authorities may Make Bye-Laws as to.—"A. S. I." writes:—"I am an Inspector of Nuisances to an Urban Authority. Will you please advise:—(1) Can my Council make bye-laws in relation to the keeping of swine so as to regulate their distance from dwelling-houses, and as to cubic space, and as to lighting, ventilation, and drainage? (2) Can you tell me of a town where such bye-laws have been adopted? (3) Can my Council stop anyone from keeping swine after a date to be specified by them? (4) Can you tell me of any book from which I could draw up bye-laws as regards the keeping of swine?"

Answer.—(1) An Urban Council may make bye-laws for the prevention of the keeping of animals (swine, &c.) on any premises so as to be injurious to health under Sec. 44 of the Public Health Act, 1875. Such bye-laws usually prohibit the keeping of swine or the depositing of swine's dung within the distance of 100ft. from any dwelling. This bye-law applies whether the swine are a nuisance to any person or otherwise, and applies to existing piggeries as well as to future ones. (2) Such bye-laws are in force in most towns in the kingdom, and the querist is advised to communicate with the Inspectors of any half-dozen towns for a copy of their bye-laws in force with regard to the keeping of swine. (3) No. But after the adoption of the bye-laws and their confirmation by the Local Government Board as required by Sec. 184 of the Act of 1875, they cannot be kept within the prescribed distance as stated in the bye-laws. But an Urban Authority cannot absolutely prohibit the keeping of swine. The provisions of Sec. 47 of the Act of 1875 may also be referred to. (4) Knight's "Annotated Model Bye-laws," price 12s. 6d., or Handford and Mackenzie's "Model Bye-laws" (in two vols.), price 25s. should be obtained. These books each contain model bye-laws which can be adopted as to the keeping of animals and numerous other subjects. Either of the books may be obtained from the office of this journal, post free on receipt of the published price.

STANLEY

Government Contractors.

Makers of Mathematical, Drawing and Surveying Instruments of every Description.

Gold Medals at the Great Exhibitions. Catalogues post free.

Addres W. F. STANLEY & CO., LTD.,

WASTE WATER CLOSETS

Easy access, powerful flush.

SANITARY TUBES

3in. diam. to 42in. diam.

GLAZED BRICKS

White Salt and all Colours.

ILLUSTRATED CATALOGUE ON APPLICATION.

JOSEPH PLACE & SONS, LTD.
DARWEN, Lancs.

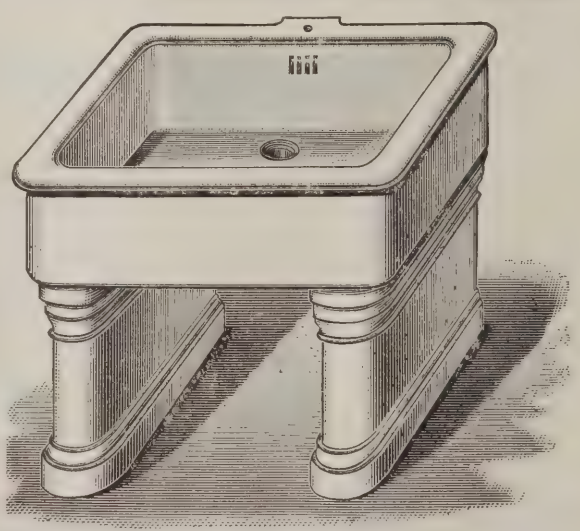
CRAIG'S WHITE GLAZED FIRE-CLAY SINKS

On White Glazed Fire-Clay Supports.

In appearance nearly equal to Porcelain, which they greatly excel in strength and durability. Admirably adapted for use in Kitchens, Sculleries, Butlers' Pantries, Laboratories, &c. Extensively used in houses of the better class, and in many important buildings throughout the country during the last thirty years.

Adopted by H. M. Board of Works, H.M. Commissioners of Prisons, &c.

Awarded First Prize Medal by the Sanitary Institute of Great Britain



J. & M. CRAIG, Ltd., KILMARNOCK

SOCIETY OF ENGINEERS.

At a meeting of the Society held on Monday, March 4th, Mr. Charles Mason, President, in the chair, a paper on "Notes on Certain Details of Drainage Construction" was read by Mr. Gerard J. G. Jensen, who said that the subject was not unfamiliar to the members of the Society, as a few years ago an excellent paper on "The Drainage of Town Houses" was read before them by Mr. G. M. Lawford.

In preparing the present paper the author has, therefore, endeavoured to avoid repetition, and to confine himself to certain details of drainage construction which might serve to amplify Mr. Lawford's paper, and which, at the same time, might give rise to a profitable discussion upon points which are frequently misunderstood, or which have not received the attention that they undoubtedly deserve.

Chief amongst the details of construction which may be brought under notice are a number of those pertaining to ventilation pipes. As with soil-pipes, so also with ventilation pipes, the materials made use of in their construction are, it may be said, confined to lead and iron. In the southern counties lead is perhaps the material mostly used; but in the north—from Lancashire upwards—iron soil-pipes and ventilation pipes are—in the author's experience, at any rate—in preponderance. While the suitability and efficiency of iron for soil-pipes cannot be denied, the use of iron for ventilation pipes is, the author submits, most inadvisable.

Fig. 1

Fig. 2

Fig. 3

The interiors of soil-pipes through which there is a flow of sewage are, almost from the commencement of their life, coated with a greasy film of a slime-like nature. This film, so long as it remains moist—as it invariably does when the soil-pipes, or even only the drains, are in use—effectually protects the interior surfaces of iron soil-pipes against corrosion. Should it fail and corrosion actually take place, the scales of rust falling into the pipe will be cleared away by the next flush of the closet. At the worst, should the rust accumulate sufficiently to cause a stoppage, the fact will soon be indicated by an overflow of sewage from the closet basin; when, doubtless, even the most indifferent householder would cause something to be done.

None of these considerations are applicable to ventilation pipes. There being no flow of sewage through them, no protective film will be formed. If of iron, even though the pipes be treated by one or other of the processes designed to protect them against corrosion, ventilation pipes will soon begin to rust in the interior, and the scales of rust falling into the pipes to the next bend or offset, will accumulate and cause a stoppage at that point, there being no flush to remove the scales. Once blocked, the ventilation of the drainage system will be partially or totally, and possibly permanently, interfered with, for the number of householders who cause their drains to be examined periodically is still, unfortunately, small.

To obviate stoppages by rust, rust chambers or pockets (Figs. 1 and 2) are frequently fixed on ventilation pipes at the points were the blockages would be most liable to occur. This course is certainly advisable, and should invariably be adopted when the pipes are of iron. In the author's opinion, however, the proper cure for the evil lies in the avoidance of iron piping, for apart from the fact that prevention is better than cure, the continuous corrosion which takes place in iron ventilation pipes seriously weakens their strength, and sooner or later necessitates their replacement. The employment of lead, and lead only, for ventilation pipes may, he thinks, be advantageously carried so far even as to include those portions of soil-pipes which act purely as ventilation pipes, when, owing to cost, strength, or other considerations, the soil-pipes proper must be constructed of iron; unless, indeed, lead-lined iron pipes are made use of for the whole stack.

It is a generally accepted rule amongst sanitary engineers, that ventilation pipes should be fixed, as far as possible, in straight lines and with as few and as easy bends as possible. The reason for this is obvious; since bends, by increasing friction, seriously diminish the ventilating action of the pipes, and this to such an extent that it is estimated that a single sharp bend or angle may reduce the air current by about one-half. Bends in some shape or other cannot, however, always be avoided, and it would, therefore, be well to consider means by which their evil tendencies could be minimised or neutralised. This, the author thinks, could be arrived at by suitably increasing the diameter of the pipes at the points at which bends occur. The idea has only recently occurred to him, and not yet having had an opportunity of carrying out experiments thereon, he is unable to give any definite views on the subject. It is not improbable, however, that some of those present may have had similar ideas, and that of these, some, at least, may have been tested in practice. If such be the case, it is hoped that those present who have made any such tests will give the results of their experience in discussing the present paper, or that, in the opposite case, they will give their views upon the author's suggestion.

Although much has already been written and said as regards the desirability of providing outlet ventilation pipes with cowls, the subject still remains debated. The deleterious effects of cowls which provide shelter for bird nests, which in time refuse to respond to the winds or which prove a fruitful source of annoyance by their noise, are so well known as not to require recapitulation. All these evils, some maintain, may be readily avoided by making use of a cowl which is not liable to them, and which is reliable under all conditions. Whether such a cowl actually exists outside the minds of patentees is perhaps questionable, but it may prove interesting to record a case in which a cowl which, at the time, thoroughly fulfilled its duties, proved a source of danger by its very efficiency. This cowl was fixed upon the outlet of a soil-pipe which received the discharge of two closets, and it so happened that whilst the cowl created an upward current in the pipe, the discharge of the lower closet tended to create an equally strong downward current, with the almost invariable result that the water contained by the trap of the upper closet was sufficiently syphoned out to destroy the seal of the trap. This experiment tends to strengthen the opinion which the author has long held, that the use of cowls should be avoided, and that nothing can exceed in efficiency a copper-wire guard (Fig. 3) as a terminal for soil-pipes, if not also for all other ventilation pipes. This opinion applies equally to those cowls which are designed to prevent "blow-downs," and which are advocated by many. If such a cowl is efficient, then the resistance which it offers to a downward current of air, created by the discharge of a closet, must be overcome. If it is not, the probability is that syphonage will take place. The free ingress of air to the soil-pipe at the right moment is much more important than the extraction of a large quantity of air or the prevention of an occasional back-draught.

Whilst, theoretically, there should be little or nothing obnoxious or dangerous in the air discharged by the outlet ventilation shafts of skilfully-designed and efficiently-constructed drainage systems, yet it is desirable that the openings of these pipes should be placed in positions in which the liberation of foul gases would be attended by the least possible risk of danger to health. There are times, even in the most perfect system of drainage, when, owing to a temporary insufficient supply of water or from some other such cause, a certain quantity of sewage is unduly retained in the drains, and there permitted to putrefy. There are also drains in which, owing to scamping on the part of the contractor, or accidental error on the part of the designer, the retention of decomposing sewage is the rule rather than the exception. In such cases, if it has been the designer's invariable rule to select, with the utmost care, the points at which outlet ventilation pipes should terminate, little harm may result. If, on the other hand, the terminals have been placed at the most convenient (as against the most suitable) points—irrespective of the positions of windows or other openings into the house or of the prevailing winds, the results may be serious.

It is unfortunate and hardly creditable that the relationship between emanations from ventilation pipes and health should hitherto have received such scant attention from engineers, medical men, and others interested in sanitation as to leave the subject utterly vague. There are no facts from which to determine the smallest distance from a window at which it would be safe to liberate these emanations. There is nothing to show whether that which would be a safe distance or height in one case would be equally so in another. Nor, even, is there any positive knowledge as to the manner in which drain and sewer air is detrimental to health. The plausible suggestion that the ill-effects of drain and sewer air are due to their action in conveying specific germs of disease has been, if not disproved, at least rendered extremely doubtful by practical experiment and experience. That they owe their evil properties to their gross chemical composition or to any one or more of the gases known to be present, has, further, been disproved by Dr. Alessi's experiments. The probability now is, therefore, that the human system is affected either by the presence of some poisonous gas which has so far escaped analysis or that there is some toxic principle present which up to the present has proved itself too subtle to be detected. Whatever the cause, however, there can be little doubt as to the effect of inhaling foul gases given off by ventilation pipes. No specific disease will, perhaps, be communicated, but the constitution will be so lowered and prepared as to fall a ready prey to a number of more or less serious illnesses. This fact was strikingly brought out by the experiments of Dr. Alessi, in which he proved that guinea pigs and rats, which are naturally immune to typhoid, proved ready victims to the fever when prepared for it by exposure to emanations from a soil-pipe.

Granted this elementary and unsatisfactory state of knowledge, it is at least desirable that the engineer and architect (for architects also design systems of drainage) should err, if at all, on the side of safety. That this is not always the case is, unfortunately, only a matter of too common experience. As an instance, the author may mention that he was last year called upon to inspect the drainage of a large school in which some two hundred pupils are housed, and in which epidemics of follicular tonsilitis have periodically raged. Structurally, he found the drainage perfect. Cost, apparently, had been (as it rightly should be) a minor consideration, for the best possible materials, and, apparently the most skilful labour—even to the point of extravagance—had been employed. Although the drainage was extensive and hundreds of various fittings were fixed in the different buildings, there was not so much as a slight leakage. With the design the case was altogether different. The drains were excessive in size, laid with insufficient fall, insufficiently ventilated and practically unflushed. As a consequence they were in a highly offensive condition. The gases so generated in the drains were discharged by a number of ventilation shafts which, almost without exception terminated—and do so now—in close proximity to and on a level with windows, the majority of which are dormitory windows.

An analysis of the cases of tonsilitis which occurred at that time and during one or two outbreaks since, showed that the cases were most numerous in the dormitories most affected by the ventilation pipes; that they were smaller in number proportionately as the dormitories were less exposed, and that one dormitory which has not a ventilation shaft in the immediate vicinity of windows which might affect it, had, as far as was known, entirely escaped. Now these facts are remarkable, since the pupils drink the same water and milk, eat the same food, and mix together freely during the day. That the tonsilitis was caused by the ventilation pipes directly is, of course, hardly probable, but that they predisposed the pupils to its attacks can, in view of these facts, hardly be doubted, even though the infection may have been imported in the first instance, and subsequently communicated from one pupil to another.

As a result of his inspection and investigations, the author made certain suggestions for minimising the risks to which, in his opinion, the drainage gave rise; but, as these were not adopted, it is presumed that the school council does not share his views. That they should not have been agreed to by the designer (the architect by whom the buildings and their drainage had been designed), was, perhaps, only to be expected, but it is worthy of note that one of the reasons given for this want of agreement was that there exists a ventilation pipe within a short distance of the windows of the designer's house, and that neither he nor his family had experienced any ill-effects from that source. Such an excuse would, on the one hand, be impossible, or, on the other, more convincing, were generally accepted and reliable facts and investigations available which could carry weight with impartial minds. Meanwhile, the evils at the school referred to not only continue, but are probably even being aggravated. A sanatorium has been built and provided with two drain-ventilation shafts which terminate in proximity to and on a level with the ventilation openings of the wards. What, if any, effect these will have on the patients remains to be seen, but the pity is that the experiments may involve human suffering, and that the subjects to be experimented upon are not guinea pigs, nor rats, but human beings.

The subject of ventilation pipes, in their relation to health, then, is one demanding the most careful study and observation; more especially since it is now not unusual to ventilate sewers also in proximity to the roofs and windows of houses; either by special ventilation shafts, or, as in some districts, through the house drains. Whilst experiments would perhaps be most conveniently carried out by municipal engineers and Medical Officers of Health working together for their own authorities, or by some such representative body as the Sanitary Institute, there is no doubt that the individual efforts of engineers generally would be productive of much good, and lead towards a solution of the problem. Until that is reached, it will be well to assume the worst, and to endeavour to guard against it, even at the cost of appearance and convenience. Who can say but that, by giving proper attention to the terminals of ventilation pipes, it may be possible to further increase the well-being of the community, and to further reduce the death-rates which have been already lowered by modern sanitation?

Coming now to anti-syphonage pipes, the author desires to draw attention to its two extremities. In the first place, it would appear that but scant attention is frequently bestowed upon the connection of the anti-syphonage pipe with the trap which it is to serve. More often than not it is found that the pipe has been branched in at the very spot at which it is most predisposed to blockage; that is, on the crown of the trap. By reference to Fig. 4. which shows such a connection,

Fig. 4

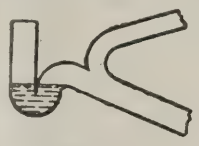


Fig. 5

it will be seen that whatever passes through the trap with any degree of force is almost certain to be washed into the anti-syphonage pipe. That this actually does take place is only too fully proved by the number of stopped-up anti-syphonage pipes daily met with. The evil can easily be avoided by fixing the pipes at a short distance from the crowns of the traps, as indicated in Fig. 5. In this connection it is satisfactory to note that the evil has been provided against in the London County Council's proposed new bye-laws, in which it is required that the anti-syphonage pipe shall be connected with the outlet of the trap at a point not less than 3in. and not more than 12in. from the highest part of the trap. It is further required that the connection should be curved in the direction of the flow, as illustrated in Fig. 5.

As regards the upper extremities of anti-syphonage pipes, the common practice is either to continue them up to the same level as the soil or waste pipes in connection with which they are fixed (see Fig. 6), or to branch them into the latter at a height of a few feet

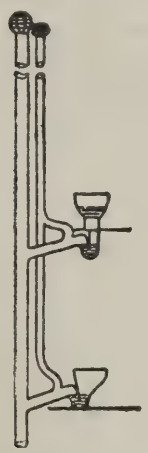

Fig. 6

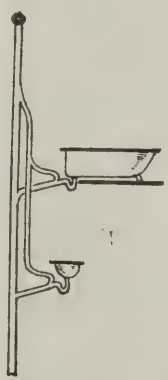

Fig. 7

above the level of the highest fitting on the stack. This method is illustrated in Fig. 7, and the author submits that it is the one which is by far to be preferred. By adopting it, the intake of air for the anti-syphonage pipe is practically brought much nearer to the fittings than would otherwise be the case. The air would, for some distance, be drawn through a comparatively large pipe, resistance by friction being thereby reduced. At the same time some benefit will be derived by the inrush of air into the stack pipe which follows the discharge of a fitting. The system is also the cheaper one, owing to the piping and fixing saved.

Although progress in the science of arranging and constructing waste pipes cannot be said to have lagged behind progress in other portions of the drainage system, there is perhaps no other part of the sanitary arrangements of buildings in which so much conservatism has been shown. Certainly, no other reason than conservatism can be ascribed for the continued construction of waste pipes from the upper floors upon that ancient and reprehensible plan which provides an open hopper head upon the main waste pipe at each point at which it is desired to branch in a waste pipe from a fitting (see Fig. 8). That the system is a fruitful source of nuisance must be evident to all who have given the subject a thought.

Two or three waste pipes of small diameter, conveying, possibly, highly offensive liquids, are arranged to discharge with the utmost possible amount of splashing into a comparatively large open hopper, whence the discharge is carried to the next hopper, through a pipe far too large for the purpose, and there again permitted to splash. This is repeated several times, according to the number of floors or fittings in the house, after which the waste water is allowed to find its way into a gulley

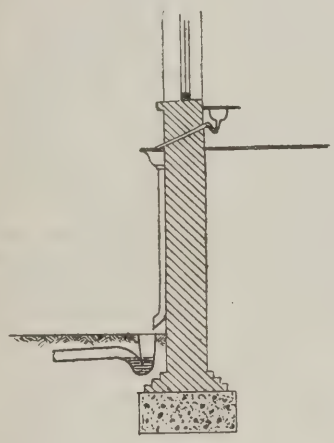

Fig. 8

trap, or possibly into an open, 18in. long channel leading to a trapped gulley. This splashing and the inefficient flushing to which these stack pipes are subjected soon permit the hoppers and piping to become coated with soap-suds, grease, and other organic matter. The emanations from these are free to issue at each hopper head, and thence to be drawn into the house through the windows, in proximity to which the hoppers are usually fixed. Nor, indeed, is decomposition necessary to render the waste pipes offensive, since it is but necessary to discharge some cabbage water or other evil-smelling waste water into the pipe at one floor for the fact to be immediately evident on the various other floors of the building. It is perhaps under the, at present, fashionable flat-life that the full benefit of the system is experienced, and it must be a source of great satisfaction to the cooks to know exactly what the various families in the building are about to eat; in so far, at least, as it is possible to judge by the discharges of the kitchen sinks.

(*To be continued.*)

PORTSMOUTH is face to face with a difficulty. The Drainage Committee applied to the Admiralty to grant additional time for the discharge of the town's sewage into the receiving tanks at Eastney, and while no direct reply has been sent, the Committee has received from the Admiralty a letter to the effect that if the necessary work for the discharge of the sewage within the stipulated time is not proceeded with the Treasury will probably withdraw its contribution to the sanitary rate. This means a loss of £20,000 per annum, and the Committee has therefore decided to recommend a new scheme of drainage, involving an outlay of £150,000.

EPIDEMIOLOGICAL SOCIETY.

At a meeting on February 15th, Dr. P. Manson, C.M.G., F.R.S., president, in the chair, a paper was read by Dr. A. Newsholme, on the "Epidemiology of Scarlet Fever in Relation to the Utility of Isolation." He admitted that the problem was, in the present state of our knowledge, insoluble, but its discussion would serve to indicate the proper lines of inquiry and of safety in practice. Though the micro-organism of scarlet fever had not been certainly identified, there could be no doubt as to its existence. It was killed by heat and disinfectants, and the disease was communicable by personal intercourse, fomites, and vehicles as milk. Until, therefore, we knew more of its natural history, it was obviously our duty to combat it by the only means at present available, disinfection of things, and the isolation of persons affected. One notable feature of the disease was that of the regular succession of cyclical waves of prevalence and mortality; in pre-notification years we had but the latter to guide us, but now we could observe its prevalence and fatality. From 1859 to 1883 the death-rate never fell below 0·28 per 1000 of the population, except in 1873, when, after a period of excessive mortality it was 0·19. In the years of maximum mortality it had been 1·28, 1·71, 1·87, and 1·06. Since 1884, however, the highest mortalities had been at the rates of 0·36 and 0·37, and the lowest 0·19 in 1899, and in 1900 only 0·08 per 1000, though these had been in years of excessive prevalence.

This change, though coinciding in point of time with the practice of isolation in hospitals, could not be wholly ascribed thereto, for it had been observed more or less on the Continent and in America, where such isolation had not been adopted. In Prague the death-rates in the ten years preceding 1884 had ranged from 1·30 and 1·33 to 0·19 and 0·20, and in the ten years following from 0·94 to 0·17. In Christiania between 1860 and 1883 the maxima were 3·05, 2·58, and 2·19, and the minima 0·2, 0·03, and 0·04; and between 1884 and 1893 1·36, 1·30, and 1·23 and 0·23, 0·24 and 0·26. In Berlin there was an improvement from an average of 0·50 to 0·80, and 0·32 to 0·03; in Paris the mortality has always been remarkably low, 0·07 to 0·19, although the death-rate from diphtheria was higher than in any other city of Western Europe. In Boston, U.S., where diphtheria was even more rife, and in Montreal, the years of highest scarlatina mortality corresponded with those of the lowest from diphtheria, and *vice versâ*. This might suggest a complementary relation between the two diseases; but in Berlin and Christiania the years of highest mortality from each had coincided; and in New York they had coincided and alternated at different times. The extraordinary range of the oscillations in the mortality from scarlatina in Christiania was characteristic of communities in which no isolation was attempted, the extreme minima following extreme maxima indicating the exhaustion of susceptible material for a time. Though the better sanitary conditions of the people —taking the word in its widest connotation, and including the higher standard of living among the masses— had been productive of inestimable benefits in all civilised communities, it could not be shown to have contributed to the lessened mortality from scarlatina, which was far from being universal; but from a comparison of English towns with Christiania and Boston, we were justified in concluding that isolation of cases did at least have the effect of protracting the course and moderating the severity of each cyclical epidemic. But we must not be hasty in assuming that the attenuation of the virulence of the disease, as seen in the reduction of the fatality (in some years and towns to less than 1 per cent. of the hospital cases) would be permanent; for the like cycles of fatality had been observed at the beginning of the nineteenth century, when the improvement was ascribed by Dr. Graves to the depletory method of treatment, until he was disillusioned by the recurrence of its former virulence. And even now malignant cases were (though rarely) met with, but that these were due to any intensification consequent on so-called aggregation of cases in hospitals he could not allow in the absence of an iota of evidence. Nor could he assent to the general belief that the low mortality was wholly due to this lessened fatality, for a comparison of the rates of sickness mortality and fatality in years of maximum and minimum prevalence in Christiania from 1860 to 1893 did not show any constant or progressive improvement in this respect. The sickness and mortality per 1000 population and the fatality per cent. for the minimum years averaged 1·44, 0·166, and 9·3, and for the maximum years, 11·25, 1·79, and 17·6, the means for the whole period 1861 to 1890 being 5·51, 0·66, and 12·1. The statistics of Boston gave similar results, though the rates were more uniform, and the means for 1877 to 1895 were 3·28, 0·30, and 9·0 respectively. In London the fatality had sunk from 5·1 in 1891 to little over 2·0 in the last two years. In all inquiries of this kind it was absolutely imperative to compare years of maximum prevalence in one town with the same in others, and those of minimum prevalence and mortality in like manner. The statistics of hospital cases and of those treated at home should be kept distinct, for while there was no question as to the actual fatality among the former that of the latter was always open to doubt from the fact that a large proportion were never notified; the result being that their number was greatly under-estimated and their fatality exaggerated. Thus only could one explain the alleged fatality of 28·5 per cent. for home cases at Huddersfield against 1·5 per cent. in the hospital. In the houses of the lower and lower middle classes isolation was impracticable, and if the removal of the first case did no more than delay the contraction of the disease by the other children for a few years it would affect the general mortality favourably, the fatality being greatly influenced by age.

To determine the extent to which hospitals tended to check the spread of the disease, he had been collecting statistics, too few, as yet, for positive conclusions, but sufficient to indicate the lines on which such investigations should be conducted. Taking a number of houses, (*a*) from which the first case had been removed so soon as notified, or (*b*) not until secondary cases had appeared, and (*c*) where the patients were treated at home, he noted and tabulated the numbers of subsidiary cases in each class, the period that had elapsed between the onset of each, and of that immediately preceding, as well as since its removal; the number of persons in the same families, and in other families occupying the same houses, under and over twenty years of age, who escaped; with the attack rate for each during the rise and decline of an epidemic, and other data, all of which were greatly in favour of hospital treatment even in their crude state, while every proper correction or revision made them more so; *e.g.*, most of the cases treated at home were so because there was ample room for isolation without removal, or because there were no other children in the houses to whom the disease could spread; and, on the other hand, secondary cases appearing later than a week after the removal and before the return of the first, could not be due to personal infection from it; and in many the patient was not removed until too late for prevention, some, indeed, not until the second or third weeks. As to the alleged higher mortality among "return" cases, even when properly so called, it was a well-known feature of the disease that successive cases in a family progressed in violence, especially when treated at home.

Mr. Shirley Murphy defended isolation hospitals as removing one means of communication, though others remained to be discovered; statistical results

from comparison of isolating and non-isolating towns, apparently against the former, must be falsified by errors of method or by ignoring local circumstances as well as cyclical variations of prevalence and mortality. In 1893 when from the seventeenth to the twentieth week the Metropolitan Asylums Board failed to meet the demand, and many patients were treated at home, the number of secondary cases rose rapidly.

Dr. Franklin Parsons pointed out that it was but recently that hospital isolation had been at all generally adopted, yet the mortality from the "isolated" diseases had sunk far more than that from measles and others that were not, and it was evident that the aggregation of cases and concentration of the infection was greater in a confined room than in a hospital ward.

Dr. P. Boobbyer (M.O.H., Nottingham) fully agreed with Dr. Newsholme and others as to the fallacy introduced into all statistics of towns with and without isolation by the non-recognition of cyclical waves of prevalence and of fatality and of local conditions, sanitary and social, but he wished to emphasise one factor that had been wholly ignored—the influence of neighbouring towns and villages. What availed the efforts of a Municipal Authority when the teeming population of surrounding districts, insanitary, and in which no precautions whatever were taken, poured daily into their factories and markets? But even the towns that were credited with the best work did less than they might do, or were supposed to have done. How else could one explain the huge discrepancy between the known death-rate of 1·5 per cent. among the hospital cases and the alleged but incredible rate of 28·5 per cent. among those treated at home, given for Huddersfield, except by assuming, *inter alia*, that 90 per cent. or more of the latter were not notified at all? Perhaps the hospitals would never achieve what was expected of them, for scarlet fever might be but the manifestation of one phase in the life history of an organism of which the others, parasitic or saprophytic, were unknown. He had long recognised the greater severity of return cases; but among 1200 so-called in one year only sixteen had died. From one orphanage sending all its sick to hospital no return cases had been received, while in another, where four had to be refused for want of room, forty-two secondary cases followed.

Dr. Louis Parkes pointed out the economic advantages of hospital isolation in enabling the parents and others to follow their usual employments, and suggested that the possible presence of the microbe in apparently healthy throats might be a source of infection, as it was in the case of diphtheria, that notification and isolation could not prevent.

Dr. Kenwood, considering hospital isolation indispensable for the poor, protested against the indiscriminate admission of patients of all classes, to the exclusion, virtually, if not officially, of those suffering from far more fatal diseases. In his district of Finchley the children of the poor died of diphtheria while the beds in the hospital were filled with scarlet fever cases, some coming from houses rented at £100 per annum. Half the expenditure of the Metropolitan Asylums Board thus spent might much better be devoted to the medical inspection of schools and other purposes. Even measles was at the present time more fatal than scarlatina; indeed, he had had several hundred cases of scarlet fever through his hospital in the course of eight years without a single death.

Dr. E. F. Willoughby expressed his regret that in this discussion, and in that in "another place," no reference had been made to the age constitution of the populations of the towns under consideration; for scarlatina being a disease of early life, and rarely fatal after the tenth year, the mortality in a town must be greatly influenced by it; and for scientific, though not official, purposes might well be calculated on the number of children living under that age, since, to take an extreme case, they contributed 24 per cent. of the total populations of London and that of Berlin, but only 12 per cent. of that of Paris; so that equal death-rates per 1000 population would indicate a mortality in Paris twice as high as in London or Berlin among those who were susceptible, and to whom the mortality was practically confined.

After some remarks by Drs. Bulstrode, Sweeting, W. A. Bond, and Theodore Thompson, the President defended what Dr. Kenwood had called indiscriminate admission on the grounds of the difficulty of drawing a line as to eligibility, since a man's occupation was of more importance to the public than his income. He had sent his children to a hospital in the interests of his practice and patients. The suggestion of a parasitic phase of scarlet fever in other animals was favoured by its remarkable limitation to temperate climates, for it was a character common to all diseases of that nature to be restricted to particular climates or regions.

Dr. Newsholme said that Dr. Millard's error consisted not in the shortness of the period on which his statistics were based, but in his method of applying them, which ignored the different years of incidence of the maximum of prevalence and of mortality in different towns. He maintained that all ratepayers had a right to hospital treatment, which he believed was always better, but if any selection of cases were made it should be based, not on the social position of the families but on the risk of the spread of infection in each case. He entirely agreed with the importance of taking the age constitution of a population into consideration in comparing one town with another, but had not as yet been able to obtain the information desired by Dr. Willoughby. He thought that Dr. Kenwood's remarkably low mortality might be due to his indiscriminate admission of cases, and that its limitation would lead to a recrudescence of the fatality in future.

CLEANSING BACKYARDS.

The following handbill is periodically circulated among the residents of Batley, and has helped materially to improve the condition of the district.

Borough of Batley, Sanitary Department.

The Sanitary Committee of the Batley Corporation urgently invite the co-operation of the inhabitants of this borough in taking steps to obviate as far as possible the great nuisance and injury to health arising from the putrefaction of animal and vegetable matter. Fish bones and heads, the entrails of fowls or rabbits, the peelings of potatoes, the husks of peas, cabbage leaves, &c., should not be deposited in the ashpits, but should be placed at the back of the fire, or underneath the fire-grate until dried, and afterwards be put upon the fire and consumed. No smell will be experienced if this is properly carried out.

All slops should be poured down the drains, and not thrown into the ashpit.

The Committee trust that occupiers of houses will aid them in promoting the health and comfort of all by invariably adopting these simple precautions.

By order,

J. Lindley,
Sanitary Inspector.

Market Place, Batley.

During March, Messrs. P. S. King and Son, of Orchard House, Westminster, will publish a new edition of Mr. W. Walter Crotch's book on "The Cottage Homes of England." The book has undergone a complete revision, and will contain a considerable amount of new matter.

INLET VENTILATION.

The occurrence in this country of three deaths from poisoning or suffocation by gas burnt in insufficiently ventilated rooms, within the period of two months, has once more brought the question of ventilation to the public notice. In last week's *Engineer* there appeared a valuable article on the subject, in which the need for inlet ventilation is clearly set forth. After enumerating the circumstances of the three fatalities, the writer goes on to say :—

It must be taken as a fundamental principle of hygiene that in bedroom, bath-room, dwelling-room, or kitchen, each and every gas stove must be fitted with an arrangement which carries the products of combustion into the outer atmosphere. Even the "practical man" never ventures to deny this proposition in plain language. He only protests that a spare chimney of the house is not always available in the corner of the room where the stove or boiler is to be placed; that if he erects a flue, sometimes it will not work; therefore, forsooth, it is better to omit the flue altogether, and request the user to open his window top and bottom. If he does not want to open his window, let him put in an outlet ventilator, and trust that the wind will never blow it shut at the critical moment. Of course a short flue designed and erected by an ignorant amateur or a rule-of-thumb workman does not always produce the desired up-current of air; sometimes it yields a distinct down-draught, more often it is almost idle. To design a trustworthy ventilating shaft outside a tall house with other houses close at hand, with sloping roofs in all directions, with currents of air and wind blowing in different ways at the same time, is a matter requiring much skill; but it can be done. Occasionally the difficulty is really to prevent an actual downward current of air in the chimney, for this may be determined by a variety of circumstances. The flue may act as the short leg of an inverted syphon, of which one of the brick chimneys of the house is the long leg. Sometimes the long leg may be the well staircase of a lofty building. Much more frequently the flue is merely inoperative because, although it works satisfactorily as the long leg of a syphon when it is given a fair chance, when the doors and windows are closed, no alternative short leg —no air inlet that is—has been provided.

A striking illustration of the way in which the central staircase or lift-well of a tall block of offices or flats will sometimes act as a regular exhaust shaft to the whole building has come under our notice at the moment of penning these lines. It occurs in a well-known spot in central London where the house contains four or five floors of offices. When the tightly-fitting swing doors leading from the street into the main hall are closed, the current of air rising through the stair-well is sufficiently powerful to overcome the up-draught of any chimney heated by an open coal fire on the ground floor; and when the door leading from the inside hall to one of the offices is opened, all windows in that office being shut, the suction of the staircase draws air and smoke down the private chimney, through the office, out of the door, and up the public staircase. When the hall-to-office door is closed, the fire burns and the chimney draws sufficiently well; presumably because the "vacuum" in the room is so high that air is sucked in even through the well-fitting window frames; but immediately that door is opened the line of least resistance is in the direction we have described. This is a case of what may be termed illegitimate down-draught. The private chimney of itself is not so faultily designed as to yield a natural downward current, it is only damped at the base by absence of inlet ventilation; but when it is placed in connection with a more powerful exhausting machine, of necessity it succumbs to the action of its stronger rival. It should be observed that a well staircase tends to produce opposite effects at the bottom and at the top of a tall building such as we have been discussing. Its exhaustive properties cause it to damp or overcome the power of the chimneys of the lower floor rooms; near the roof it often assists the chimneys by helping to drive air into the several apartments ready for the private flues to extract. Downstairs it produces a negative pressure, upstairs it produces a positive pressure, which have to be added algebraically to the pull of the individual chimneys.

If the reader will turn to those technical journals which make a special point of answering questions and teaching elementary applied science, in almost every issue now-a-days, he shall find an inquiry as to why a certain chimney or flue will not draw. It may be the chimney of a coal fireplace; it may be the flue of a gas stove. In nearly every instance the inquirer describes the trouble as down-draught; in nearly every instance his own words show it to be nothing of the kind. The replies, when they are given correctly, are almost invariably couched in identical terms: Your chimney does not draw because you have not put an inlet ventilator in your room. You cannot extract foul air from a closed apartment if you do not replace it by an equal volume of fresh air. The point is rudimentary; but we are compelled to affirm that it is one which has been overlooked by many architects and ventilating engineers in the past.

Hitherto the bulk of our population have lived in single, low, £40 or £50 town houses, each with its own front door and hall, with light and badly-fitting doors and window frames, with floors cramped together of green wood which quickly gapes into wide openings. However much the occupier strives to produce a vacuum in his rooms, he cannot succeed; in spite of his best endeavours air enters the various cracks and crevices of his house to an extent which defeats his involuntary attempts at suicide, and keeps him in good health. Now there is a move to lofty flats, better and more stoutly built, with doubly or trebly inclosed halls, with no shaft-like staircase inside the private dwelling, with well-constructed door and window frames. When the windows are shut, each flat is practically closed against the atmosphere except through the chimneys of its several rooms; and when the servants light the kitchen fire, the fresh air which it needs is drawn down the chimney of an adjacent room. A gas stove in the bed or sitting-rooms, or a geyser in the bath-room connected into a chimney, will not pull against a dwelling-room coal fire, or the stronger draught of the kitchener; and there is a downward current of air or, as the case may be, of air plus combustion products, because the cooler chimney acts as the short leg to the long leg of the hot one. Here again the cure is obviously an inlet ventilator. Much skill and thought, however, are needed in fitting such; for unless they are placed in the proper situations, and the currents of fresh air are most carefully broken up and deflected, they produce a gale of wind which is unbearable and fraught with danger to health.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

The following meetings will be held on Wednesday, March 13th, 1901 :—

Examination and Literary Committee at 3 p.m.

General Purposes and Finance Committee at 4 p.m.

Election Committee at 5.15 p.m.

Members' Sessional Meeting at 7 p.m.

March 22nd and 23rd, Examination in Practical Sanitary Science.

HULL'S NEW DISINFECTING STATION.

The formal opening of the new Hull disinfecting station and the laying of the foundation stone of the projected West district destructor took place on February 20th, in the presence of a large gathering of the Corporation officials and the general public. The Mayor (Alderman Gelden), accompanied by members of the Corporation, drove from the Town Hall to the site of the new destructor, where a special platform had been erected, and the scaffold poles decorated with flags and bunting.

It was in October, 1899, that the City Council sanctioned the erection of the proposed station on a site covering a ground area of 3000 square yards, situate in West Dock-street, at a cost, including furnishing, of £5000. The station is isolated and easy of access, and is provided with waiting-rooms, bath-rooms, &c., containing accommodation for both sexes, to which persons who have been exposed to infection can be removed for the purpose of bathing and the disinfection of their clothing. Formerly the disinfection of bedding and articles of clothing was carried out at the municipal infectious diseases hospitals, with apparently no danger to the public health. The demolition of the Garrison Hospital, however, necessitated the provision of further suitable accommodation. The arrangements of the station are such that, where advisable, families and those who have been engaged in nursing the sick may be removed for bathing and the disinfection of their clothing, and may also be isolated in the shelters attached to the station. The station will prove a great advantage to the Port Sanitary administration, as should a vessel arrive in the port with infectious disease on board, in addition to the infected person being removed to hospital, the whole of the ship's crew and effects may be removed to the disinfecting station, whilst the ship itself is undergoing disinfection. It is considered by the Sanitary Committee that the appliances and equipment for disinfection in Hull should be as complete as scientific knowledge admits. The disinfecting station contains an apparatus known as the "Washington Lyon," of the latest design, and on the most modern and approved principles. All the most important requisites of a disinfecting station are provided, the accommodation being as follows:—Disinfection block (clothing, &c.): Receiving-room, discharging-room, disinfecting chamber for cabs, operatives' bath-room, sanitary convenience, tool store, wash-house, and boiler-house. Disinfecting block (personal): Two waiting-rooms for males, two waiting-rooms for females, two bath-rooms for males, two bath-rooms for females, two dressing-rooms for males, two dressing-rooms for females, two (discharged) waiting-rooms for males, two (discharged) waiting-rooms for females, office, sanitary conveniences, and night shelters (ten beds). Stables, &c.: Three-stall stable, harness-room, manure pit, and three cab-sheds. The Sanitary Committee have determined to take over the whole of the ambulance arrangements in connection with the removal of persons to hospital, and of infected bedding, clothing, &c., for disinfection, and its return home after completion; also for the conveyance of patients to hospital and their return home after convalescence. Adequate accommodation has been provided at the station for the stabling and sheltering of the necessary horses and ambulances used for the purpose. Houses have been erected for the superintendent and horsekeeper, who will be available at any hour in cases of emergency to undertake the removal of patients to hospital, disinfection of clothing, &c. To comply with the provisions of the Infectious Diseases (Prevention) Act, 1890, it is compulsory, on the completion of the patient's convalescence, that the house or part thereof, and all articles likely to retain infection, shall be disinfected to the satisfaction of the Sanitary Authority. The completion of the disinfecting station fulfils a long-felt want, and its complete equipment is a great adjunct to the sanitary administration of the city.

The destructor, which is of the Horsfall type, will have twelve furnaces, each capable of destroying ten tons every twenty-four hours. The carts will be raised by means of a steam hoist to an upper platform, where they will be tipped, thus overcoming the necessity of drawing heavy loads up a steep incline, as in the case of the existing destructor at Chapman-street. An incline will be provided for the return of the empty carts. Two water-tube boilers of Messrs. Babcock and Wilcox's manufacture will be provided, and, if necessary, there will be room to fix two others. It is intended to supply steam to the disinfecting station and also to the hoist. The building will be large enough for four additional furnaces, making the total number sixteen.

ISOLATION IN RELATION TO TYPHOID FEVER.

There can be no doubt that the most important step to be taken at the present time for the prevention of typhoid fever is to provide for the removal to hospital of all patients who cannot be properly isolated at home. The need for a larger number of removals is clearly shown from the fact that 244, or about two-thirds of the cases were treated at home in the past quarter. Moreover, 101 of the cases treated at home lived in houses with two bedrooms and one living-room only, and a number of these houses contained as many as seven other persons besides the patient.

The effect of removal to hospital is very great in preventing further cases in the same house and among the patient's friends and relatives. But it is also most noticeable in increasing the patient's chance of recovery. Thus, in the quarter under review, of the patients treated in hospital only 12 per cent. died, while 24 per cent. of the cases treated at home succumbed to the disease. This is not surprising when it is remembered that a great many cases occurred in the homes of the poor, where skilful nursing, suitable diet, and good hygienic surroundings are not generally available.—Alfred Hill, M.D., M.O.H., Birmingham.

British Congress on Tuberculosis.—This Congress, which is to be held in the Queen's Hall, Langham-place, in the week beginning July 22nd, 1901, has arranged, amongst other matters, for three public addresses to be delivered in the Large Hall on Tuesday, Wednesday, and Thursday of that week. The first will be given by Professor Robert Koch, of Berlin, discoverer of the tubercle bacillus; the second by Professor Brouardel, of Paris; and the third by Professor McFadyean, of the Royal Veterinary College.

Holiday Children.—Mr. J. P. Humphrey, Sanitary Inspector to the borough of Reigate, says:—"The attention of the department has been forcibly drawn to some cases of overcrowding which have occurred through the occupiers of cottages, who already have families of their own, receiving holiday children who have been sent from London by various philanthropic associations. It is doubtful if a child receives any permanent good by fresh air received in the day if compelled to sleep in a fœtid atmosphere during the night. There is also a risk of infectious illness being imported into the borough by these children, and it seems desirable that there should be some system of notification to the Local Authority by the associations in question of their intention to send such children out, and the intended destinations. Attention should be given as suggested by the magistrates, that they should always be under proper supervision."

ANNUAL REPORTS.

Clackmannan.—The tenth annual report by Dr. Nasmyth upon the health and sanitary condition of the county and burghs of Clackmannan has been issued. The county water scheme, it is stated, is not yet completed, but the temporary supply has been a great boon. During the year there were 59 cases of infectious diseases reported, as compared with 45 the previous year. There were 334 births and 168 deaths, giving a birth-rate of 26·6, and a death-rate of 13·5 per 1000 of population. Dealing with the burghs, Dr. Nasmyth states he knows of no busy commercial town in so sanitary a state as Alloa. Alva is favourably reported upon, while it is stated of Dollar that the general state of the burgh is good. For Tillicoultry improved storage for water to provide against dry summers is recommended.

Craven.—Dr. Atkinson, M.O.H. to the Joint Committee of the combined districts of Craven, has distributed copies of his annual report to the Council. A summary of statistics for the past year was given in the report in tabulated form, and showed that the rateable value of Settle for 1900 was £143,682, and the estimated population 14,340. The total births for the year numbered 346, equal to a birth-rate of 24·1 per thousand of population. Total deaths numbered 191, which was equal to a death-rate of 13·3 per thousand. The percentage of total deaths under one year was 16·2, and per 1000 of registered births 89·5. The percentage of total deaths under five years was 21·9, and over sixty-five years 20·9. The zymotic death-rate per 1000 was 0·3. The Doctor alluded to these figures as being satisfactory. The death-rate for England and Wales during 1900 was 18·3 by which Settle's 13·3 compared favourably, whilst the zymotic death-rate for England and Wales was 2·0. Settle's zymotic rate, as they would see, was 0·3, which was the least of the whole of the other districts of Craven, with the exception of Sedbergh, which was 0·0.

Sunderland.—Dr. Scurfield, Medical Officer for the Port of Sunderland, has just issued his annual report. From it we learn that twenty-four ships entered the port with sickness on board during the year 1900, which is not a large number when it is considered that 5777 vessels in all entered. Of the cases reported only three were of an infectious nature, viz., one enteric fever, one scarlet fever, and one small-pox. The total number of vessels entering the port was a decrease of 139 on that of the preceding year. Those engaged in the coasting trade numbered 4097, and in the European trade 1293, while 96 were trading beyond Europe. The gross tonnages of the vessels amounted to 2,633,937 registered tons. Of the total ships which entered the port 2751 were inspected and reported upon by the Inspector to the Port Sanitary Committee. On these vessels there were 37,080 sailors living, compared with 37,366 in 1899. The average number of men in each ship last year was 13·5; in 1891 it was 12·7. Of the 2756 vessels inspected, 95, or 3·4 per cent., were found to have one or more sanitary defects. The nuisances consisted of 38 foul or dirty forecastles or living places, and 57 foul conveniences. In every instance the nuisance was abated on the notice of the Inspector, no legal proceedings being necessary. The British ships show an insanitary percentage of 2·1 less than last year.

Thedwastre.—At the last meeting of the Distrfct Council the Medical Officer of Health (Mr. A. Butler) presented his annual report on the health of the district in 1900. The number of deaths registered was 124, or 13 per 1000; the number registered during 1899 was 111, or 11·6 per 1000. The number of births registered was 241, or 25·3 per 1000, and the number registered during 1899 was 250, or 26·3 per 1000. The infant mortality, or deaths, occurring under one year of age, was 10, as compared with 21 for the previous year. No death had been reported as occurring from zymotic causes during the year. Ten deaths were caused by phthisis, as compared with six during the year 1899, and seven during the year 1898. This, though a slight increase, compared favourably with most districts in England. During the year he had received 29 notifications of infectious diseases, as compared with 34 for the year 1899. This was a small decrease, but might have been still further reduced had the district been provided with an isolation hospital. Ten cases of scarlet fever were reported, as compared with 22 for the previous year, nearly all the cases occurring in the parishes of Beyton and Hessett. Five cases of diphtheria were reported, all of which occurred in one house. In one parish, Hessett, with a population of 353, there had been no deaths, while at Drinkstone, with a population of 390, there had been only one death, and the same was the case at Gedding, with 92, and Felsham with 374.

INSANITARY ESSEX.

The sanitary condition existing in the Maldon district of the county of Essex, despite the energetic measures taken by the Medical Officer of Health, Dr. Thresh, still continues to leave much to be desired. The district contains a large number of very old cottages, difficult to maintain in habitable repair. These do not improve as years roll on, and each year sees a certain number voluntarily closed by the owners as being beyond repair. Most unfortunately very few new ones are being erected, as they cannot be built at such a price as to render the investment remunerative. A certain amount of overcrowding certainly exists, but very few cases occur in which the Council can interfere, although there are very many families living under conditions which must efface all trace of modesty, and conduce ultimately to immorality, if not to actual crime.

Many nuisances arise from cottages having been erected on pieces of roadside waste with little or no ground at the rear. The privies and ashpits have to be very near the cottages. By more frequent inspection, and by the substitution of pail or earth closets for the old privies, great improvements have been effected, but the condition still leaves much to be desired.

The general condition of many of the private wells is far from satisfactory, chiefly arising from imperfect construction, defective pumps, want of paving around, or of a drain to carry away the waste water, and from being placed in gardens which are highly manured, often with human excrement, &c. Very few of them yield a water which can be considered pure and safe, yet it is often impossible to obtain a better supply. For example, at Tolleshunt Major an attempt was made to obtain a supply which should be under the control of the Council, but the site selected yielded a very impure water, and the only good water is a small spring or private pond at one end of the village. Possibly this may be utilised. At Ulting a scheme was mooted for piping a spring to the principal group of houses, but has not yet been carried out.

More care is exercised in connection with the supplies to new houses before a certificate for occupation is granted; but it is worth consideration whether a better construction should not be insisted upon. Dr. Thresh thinks that with a very little additional expense it would be possible to decrease the risks of pollution. Glazed earthenware cylinders might be substituted for

the dry steyning, the top should be properly domed over and be made water-tight, and the suction pipe be flanged and so inserted as to prevent surface water gaining access along the track of the pipe. A code of regulations could be drawn up, and an intimation given to each person sending in plans that the water supply would not be considered satisfactory unless the regulations were complied with.

Accumulations of refuse are very common, few houses having any kind of receptacle for ashes or house refuse, save in the more populous parishes, such as Heybridge, Tollesbury, and Southminster, where a public scavenger is employed. The usual plan is to throw the refuse into a hole dug in the garden. If this hole were at a distance from the cottage, and a little earth were sprinkled over occasionally, this mode of disposal would rarely cause a nuisance, but too often the hole is at the nearest point to the back door, and serves as the receptacle for liquid slops as well as ashes. Attempts are made to educate the people by recommending them to use the dry ashes for covering the excreta in the pails or cesspits, and to distribute the slops uniformly over the garden, but ease is considered before health, and the present existing insanitary conditions are likely to continue. Slaughter-houses and bakehouses are found generally in fairly satisfactory conditions. Cowsheds vary very much. The more modern ones are satisfactory, but some of the older ones leave much to be desired. Dr. Thresh hopes the introduction of the new water supply will lead to improvements.

THE SURVEYORS' INSTITUTION.

The annual dinner of the Surveyors' Institution was held on Monday evening at the Holborn Restaurant. Mr. John Shaw, the president, occupied the chair, and among those present were Sir J. Wolfe-Barry, Sir J. F. L. Rolleston, M.P., Sir Alexander Binnie, Mr. A. de Bock Porter, Mr. Daniell Watney, Mr. J. L. Wilkinson (general manager, Great Western Railway), Mr. D. J. Ross (City Engineer), Mr. Arthur Vernon, Mr. J. F. F. Horner (Commissioner of Woods, &c.), Mr. G. M. Freeman, K.C., Mr. R. Ellett (president Incorporated Law Society), Mr. C. J. Owens (general manager, London and South-Western Railway), Mr. Andrew Murray (City Surveyor), Mr. J. H. Sabin, Mr. T. M. Rickmann, Mr. W. A. Flaxland, Mr. J. C. Rogers (secretary), and Mr. J. W. Penfold (hon. secretary). Lord Brampton and Mr. Justice Grantham were prevented by illness from being present.

After the usual loyal toasts had been duly honoured, the Chairman proposed "The Houses of Parliament," to which Sir John Rolleston replied. Sir J. Wolfe-Barry then submitted "The Legal Profession," and Mr. G. M. Freeman, K.C., and Mr. R. Ellett responded.

In proposing the toast of the evening, "The Surveyors' Institution," Sir Alexander Binnie (Chief Engineer of the County Council), said that his profession was very intimately connected with that of the surveyors. He looked upon their organisation with pride and pleasure. It was a young institution, but was rapidly growing, and its members had appreciated what was absolutely necessary for the growth of any profession of that kind. They had established themselves, and had determined, by their influence, that their profession should be kept up to the highest mark which was possible in an advanced age like the present. They had established a library, which was the backbone of any institution.

The President said, in reply, that he did not think the public generally were aware of the position of the Institution at the present time. When it was started years ago, the first report being published in 1869, there were 200 members. The last report, published in 1900, showed a membership of between 3000 and 4000, and he was happy to say the number of members was still increasing. The accounts were in a most satisfactory condition, and after paying off the debt in connection with the new building in Great George-street, the outlay having been £31,000, there were considerable balances, The library now contained something like 8000 volumes. In regard to their Benevolent Fund, which was proposed two years ago, there was £7100 invested. He hoped that the Institution would in future continue to benefit all surveyors, and particularly young surveyors. Other toasts followed.

CORRESPONDENCE.

(*To the Editor of* The Sanitary Record.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

A GOOD RECORD.

Sir,—The following facts may interest you and your readers. The borough of Batley is a manufacturing town with a population of 32,000. For the whole year 1895 not a single death occurred from measles or scarlet fever. For the whole year 1896 not a single death occurred from diphtheria. For the whole year 1899 not a single death occurred from measles, and only two deaths occurred from scarlet fever. For the whole year 1900 not a single death occurred from scarlet fever.—Yours faithfully,

Batley, March 1st. Observer.

A CORRECTION.

Sir,—In the abbreviated report given in this week's issue of your journal of the meeting of the National Union of Sanitary Inspectors held at Oswestry, it is stated in reference to the bacteria beds that in albuminoid ammonia 80·5 per cent. of purification is effected. This should be 89·5 per cent.—a marked difference. I shall be obliged if you will kindly correct this in your next week's issue.—Yours faithfully,

Oswestry, March 1st. G. William Lacey.

THE REEVES SYSTEM OF SEWER VENTILATION.

Sir,—In your issue of January 17th you allow a reference to the Reeves system, in a report by Mr. H. Gilbert Whyatt, the Grimsby Borough Engineer and Surveyor, which I am persuaded is purely the result of an inadvertence so far as you are concerned. You will be able to judge of the untenableness of Mr. Whyatt's position in more ways than one from the enclosed correspondence, which has appeared in the *Public Health Engineer*, and which, with your usual fairness to both sides of a question, you will, I have no doubt, publish in your next issue, and thereby put your readers also in possession of the facts.—Yours faithfully,

17, Victoria-street, S.W., Wm. Brown.
March 2nd.

[copy.]

Sir,—My attention has been called to the short letter of Mr. W. Brown in your issue of January 5th. I regret that, owing to pressure of business, I did not read that issue so carefully as I might have done, and did not see it at the time.

Mr. Brown calls upon me to make good my statement as to the expense of the "Reeves system" of ventilation preventing its use being maintained for any lengthened period.

My statement was made from my knowledge of the customs of many Local Authorities in this country. A new installation (for any purpose) recommended to them is

adopted by them after full inquiries, and, as long as the Local Authority consists of the same gentlemen, is maintained regularly. In the course of a few years the composition of the Council changes; "A new king rises who knew not Joseph," a reign of economy sets in, the use of the installation is suspended for a time, and probably is never re-commenced. This applies generally to works which are out of sight (and therefore out of mind), and sewer ventilation is no exception to this rule.

I estimate the cost of a "Reeves" installation somewhat as follows:—First, there will be the alteration of the manholes, which may be anything from £5 to £10; the cost of apparatus is £10; making an initial cost for each manhole from £15 to £20. Then comes the cost of maintenance. The cost of chemicals is from £2 to £3 per annum; the cost of water spray will vary according to its local price, and may be anything from 3d. to 1s. per 1000 gallons, which works out at £3 to £12 per manhole per annum. In addition to this, there are the wages of the attendant, which will, of course, be in proportion with the number of manholes fitted up and the number of days per week that it occupies his time. Assuming that each manhole requires two hours' time per week, this will represent 104 hours per annum, or, say, £2 10s., making the annual cost per manhole from £7 10s. to £17 10s. Supposing that the Local Authority has put down ten installations, it will easily be found what a great temptation it will be to economise in this direction rather than in any other.

From the accounts that I have received of the efficiency of and the quantity of air purified by the "Reeves" system, I came to the conclusion, as I said in my report, that the system was effective; but there is no reason to withdraw my statement that Local Authorities are not likely to maintain its use for any lengthened period, for the reasons above stated.—Yours, &c.,

H. Gilbert Whyatt,
Assoc. M. Inst., C.E., M. San. Inst.,
Borough Engineer and Surveyor.

Borough Engineer and Surveyor's Office,
Town Hall, Grimsby, February 14th, 1901.

Sir,—Referring to Mr. Whyatt's letter to you in last week's *Public Health Engineer*, the objectionable passage which Mr. Whyatt sees no reason to withdraw from his report on sewer ventilation, for reasons he mentions, is: the Reeves methods "are so expensive that no Local Authority is likely to maintain them for any lengthened time." But the reasons will not stand inspection. They consist of two crude generalisations, and the first thing a student of this sewage disposal problem has forced upon him is that generalisations—even such as are not crude—are not to be too much relied upon. Mr. Whyatt's first generalisation is vague and improbable, and his second is vague and inaccurate. The first—the reference to the Joseph incident—to have any force at all, Mr. Whyatt must prove that Local Authorities have no proper interest in the life and health of the public who entrust them with the important duty of seeking out and maintaining those methods which are proved to be beneficial to the public health. By the Reeves system perfect sewer ventilation can be guaranteed absolutely. That is, under all atmospheric conditions no fouling of the air in sewers is allowed to take place. It is not at all a likely thing, therefore, that this system, once installed, and its benefits proved, any change in the *personnel* of any Local Authority would have the result of which Mr. Whyatt is so apprehensive. The officers of the public health service would have something to say before that would be allowed to happen. As to the second generalisation, which Mr. Whyatt calls "an estimate of the cost of a Reeves installation"—meaning thereby an apparatus, and not the Reeves system as a system—its equal lack of force will appear presently.

It is necessary now to explain that, no reply being made to my letter to you, appearing in your issue of January 5th, but, instead, Mr. Whyatt's report, with the same objectionable clause repeated, appeared in The Sanitary Record of January 17th, I wrote direct to Mr. Whyatt, and a correspondence ensued, in the course of which I put him in possession of certain facts about the Reeves system which I then hoped would have been used by him as a golden bridge to retire from the false position he had taken up.

I give below a summary of these facts:—

(1) That Mr. John Cooper, the Burgh Engineer for Edinburgh, reporting to his Council on the year's work of his department, in a section dealing with the question of sewer ventilation, makes the following reference in recommendation of the Reeves system: "I have to confess that after prolonged investigation I can, meantime, recommend no more effective system than that of Reeves. . . . Shafts tall or otherwise, will not be tolerated in the public streets or erected against houses."

(2) That on the basis of figures given in a paper read by one of Mr. Cooper's assistants at the meeting of the Municipal and County Engineers, Edinburgh, 1898, Mr. Reeves had shown that his system was capable of purifying a volume of sewer air equal to 4,500,000 cubic feet for 1s. 6d.

(3) That we can point to a case where we would be prepared to install our system, keep it going for twenty years, and pay ourselves out of the money at present spent on flushing the sewers, without getting adequate ventilation, and at the end of the twenty years hand the installation over to the Local Authorities without any further payment, and during the twenty years we would give an absolute guarantee against any pollution of the sewer air.

(4) That the cost of applying the Reeves system to all the sewerage of the urban populations in the United Kingdom, say 20,000,000, would not exceed £150,000 annually, including interest and repayment of capital—a small sum, comparatively, to the cost of the vaccination service alone.

(5) That the cost of maintenance of a Reeves apparatus depends entirely upon the work it has to do. In the case of Edinburgh the cost refers to severe conditions, while there are other cases where the cost is only a few shillings per apparatus per annum. Similarly, with regard to cost of installation, it may range from £5 per apparatus up to a considerable sum.

Mr. Whyatt had all these facts before him when he wrote you that he did not see any reason to withdraw his objectionable reference. It is to be hoped that he sees what he owes to himself a little more clearly now.

I see that Messrs. Stone in their letter to you, also in last week's number, make a statement which I commend to Mr. Whyatt's attention. It shows how much importance a firm of standing and experience attaches to a question which Mr. Whyatt would seem to treat as of minor importance. Messrs. Stone say:—"Of course, if Mr. Reeves really can do this (viz., purify 4,500,000 cubic feet of sewer gas . . . at a cost of 1s. 6d), then we have nothing further to say, except to express a hope that his system may soon be universally adopted, but the claim appeared to us to be so very absurd that we did not think it necessary to attempt to refute it."

Now, within the limits of Mr. Reeves' calculation, this claim is quite legitimate, and I presume that Messrs. Stone no longer see any absurdity in it. Mr. Whyatt will at least admit the cogency of this point. He must be familiar with the figures on which it was based, which were published in the "Transactions" of Municipal Engineers, the technical Press, and Colonel Moore's "Sanitary Engineering," and have never been disputed. Indeed, Mr. Whyatt goes as far as to say:—"From the accounts I have received of the efficiency of and the quantity of air purified by the Reeves system, I came to the conclusion that the system was effective."

If, therefore, Messrs. Stone have any doubt remaining as to the possibilities of the Reeves system, I commend them in turn to Mr. Whyatt.

Your readers, I am sure, will readily appreciate the value of such evidence. Neither witness can be suspected of being biassed in our favour, at least for the moment, although I feel sure that fuller knowledge would bring about a better understanding between both opponents and ourselves.

The error which Messrs. Stone have fallen into as to the quantity of sewer gas generated in London in twenty-four hours, and which, strangely enough, they make in two separate letters, does not affect Mr. Reeves' calculation in any way. It is clear from the context that both parties are dealing with the same substance, viz., not the gas generated from the sewage, which has been calculated at about 3,000,000 cubic feet, but the air polluted by such gas in all the varying proportions in which it may occur in a sewer at any particular time.—Yours, &c.,

Wm. Brown,
Managing Director, Reeves Chemical Sanitation, Ltd.,
17, Victoria-street, S.W., February 26th, 1901.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

It is singular that there should be such a very erroneous and vague notion amongst those who, it might be supposed would have known better, that all coal gas is more or less of the same lighting value, and that gas which is supplied at, say, 2s. 6d. per 1000 cubic feet, is universally considered to be, without a shadow of doubt, cheaper than gas at, say, 4s. per 1000 cubic feet. As a matter of fact, however, if gas at the latter price be of higher quality or illuminating power than that supplied at the lower price, it may be much cheaper to the consumer. Mr. W. J. Dibdin, F.I.C., F.C.S., the well-known analytical chemist, and formerly chemist and gas examiner to the London County Council, than whom—as pointed out the other day by Professor Percy Frankland in the discussion which followed the reading of a paper by Mr. Dibdin on "Coal Gas: Effect of Quality on Consumption," at the Society of Chemical Industry—"probably no one living had had so much practical experience of the illuminating power of gas, how it was developed, and on what principle burners should be constructed," has conducted a series of valuable and exhaustive experiments showing the effect of variations in quality upon the quantity of gas required to give normal illumination.

For the purpose of the experiments different qualities of gas were obtained and connected to a photometer. The quality of the gas was first carefully tested when burnt at the rate of 5 cubic feet per hour in a No. 1 London Argand burner for its illuminating power, and then burnt in various gas burners in succession, making photometrical determinations of the light and estimations of the quantity of gas consumed.

In this way it was ascertained that with a flat flame burner of recognised efficiency, viz., Sugg's table top No. 4, which gave 14·4 candles of light with 5·3 cubic feet per hour of 16·2 candle gas required to produce the same illumination, 6·1 cubic feet per hour, when the illuminating power of the gas was reduced to 15·2 candles; 6·4 cubic feet with 14·2 candle gas; 7·75 cubic feet with 13·5 candle gas; 9·7 cubic feet per hour with 12·2 candle gas, and 11·2 cubic feet per hour with 11·2 candle gas; whilst when the quality of the gas was raised to 17·2 candles the consumption required to yield the same unit or normal lighting power of 14·4 candles was reduced to 4·5 cubic feet per hour, and with 19·2 candle gas the consumption was only 3·9 cubic feet per hour.

Interpreting the variations in consumption of gas into relative cost, it was found that to obtain equal degrees of illumination with varying qualities of gas with a well-known burner—Bray's No. 4—the actual cost of gas to the consumer, on the basis of light for money, would be as follows:—

Illuminating power of gas.	Quantity of gas required to give light equal to 1000 cu. ft. of 16·0 candle gas. cu. ft.	Actual cost of gas at 2s. 6d. per 1000 cu. ft.
19·0	600	1 6
18·0	700	1 9
17·0	820	2 1
16·0	1000	2 6
15·0	1340	3 4
14·0	1800	4 6
13·0	2400	6 1
12·0	3040	7 9
11·0	3750	9 6

From this table it will be seen that, with a fall in the quality of the gas of 2 candles—say, from 16·0 candle-power to 14·0—the cost of obtaining a fairly uniform light to the consumer is nearly doubled; and with a further fall of 1 candle-power — *i.e.*, to 13 candles —the cost is 6s. 1d. against 2s. 6d., a circumstance which explains the otherwise inexplicable rise in consumers' gas bills which is so common in districts where the quality of the gas is variable. It is, therefore, plainly evident that comparisons in the cost of gas in different districts are absolutely valueless without a recognition of the *quality* of the gas in each case, for if a larger quantity of low-power gas has to be consumed to obtain a sufficient or equal light to that of a higher-power gas at a higher price, the latter may be much cheaper to the consumer.

These facts are of great importance, especially so to municipal engineers, whose duty lies in ensuring that gas companies who contract for the lighting of public lamps fulfil their contract and give the quality of gas required. It is also a fitting commentary on the necessity of Parliament prescribing the illuminating power of gas which has to be supplied by companies to the public, who require to be protected against the cupidity of many of those whose directors look upon consumers as dividend-earning machines. A considerable number of municipal engineers and surveyors are required to enforce contracts for street lighting. This, however, cannot be done, unless the Local Authority possess a photometer. Such experiments as those conducted so ably by Mr. Dibdin show how extremely necessary it is that without such an apparatus both they and the public are likely to be deceived, and it is to be hoped that the lesson will not be lost. Senex.

YELLOW FEVER IN CUBA.

One of the great advantages which sanitarians hoped for when the United States obtained control over Cuban affairs was the opportunity which would be thus presented for such a cleansing of the city and harbour of Havana as would diminish, if not entirely exterminate, that dread scourge of the tropics, yellow fever. And yet, though the city is cleaner now than it has been in fifty years, still the fever is unusually prevalent. The season which has been regarded as especially conducive to its development is the rainy season; this year this has been almost entirely absent, dry weather having replaced the usual wet weather.

The increase has been accounted for according to some by supposing that it is an apparent, not a real increase, the returns hitherto having been very incomplete; and further, by the fact that an increased number of immigrants have arrived at Havana this year. It is gratifying to note that Santiago is practically free from the disease.

The theory, advanced by Dr. Finlay, of Havana, that the bites of insects, fleas, and mosquitoes, propagate yellow fever is now receiving marked attention, and the observations of Dr. Reed and other physicians of the U.S. Army are strongly confirmatory thereof.

Surgeon-General Sternberg sent to Cuba last summer a commission consisting of Major Walter Reed, Surgeon U.S.A., Drs. James Carroll, A. Agramonte, and Jesse W. Lazear, acting assistant surgeons, U.S.A., to investigate yellow fever. Of this commission, Dr. Carroll was bitten by a mosquito August 27th, taken sick August 31st, and went through a severe attack of yellow fever.

Dr. Lazear was bitten August 16th by a mosquito from a mild case of yellow fever, without serious result. He was again bitten September 15th, and died of yellow fever September 25th.

The mosquitoes used were raised from the eggs in tubes, allowed to bite patients suffering from yellow fever and then permitted to bite Drs. Carroll and Lazear, both of whom volunteered for the purpose. If there is any instance of devotion to science more conspicuous than this, we are ignorant of it.—*Brooklyn Medical Journal.*

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

SANITATION IN HIGH PLACES.

THOUGHTFUL men have long since refused to subscribe to the dictum that the "King can do no wrong," and yet there are many details of the administrative life of Government departments which would point to the conclusion that, while they make laws and regulations for others, they refuse to be bound by such restrictions themselves. We are among those, however, who refuse to believe in the infallibility of any human organisation, or to admit that any branch of public life should be freed from the safeguards deemed essential to the health and well-being of the general community. The private manufacturer must see that his factory is suitable for the accommodation of his workpeople. Not only has he to satisfy the Factory Inspector, who represents the central government, but he must conform to the regulations of the local authorities in all matters pertaining to a proper sanitary condition of his works. In fact, in the metropolis, he has a double test to satisfy, the Borough and County Councils. The Government departments, however, claim exemption from the jurisdiction of these bodies on the ground that their needs are looked after by the Office of Works. But is this office properly equipped for the work it is supposed to carry out? Of course it has its political head, its permanent officers, and its prescribed number of clerks, but there is nothing in its constitution to qualify it for the responsibilities which such an office should undertake. It is not sufficient that those who work in Government offices should be put into fine buildings; the exterior may be of the most ornate architecture, but the interior may be little better than a pest house if the elementary principles of hygiene are totally ignored or only superficially attended to. Clerks in high places have quite as much right to consideration as artisans and girls in factories, and it is because we believe that the staff of the Office of Works, as at present constituted, is not capable of ensuring this needed protection, that we urge the necessity for immediate reform.

That the Department has some doubt about its efficiency recent events may be taken as a proof. Many have been seeking for the reason of the appointment, announced a short time ago, of Dr. Corfield to the position of Consulting Medical Officer of Health to the Office of Works. That the appointment of Dr. Corfield to such a post is a good one all will admit; but, in itself, it is either unnecessary or it does not go far enough. Thus, we have made it our business to try to become acquainted with the circumstances leading up to the new departure, and the evidence we have secured proves two things: first, the incompetency of the Department; and secondly, the need for supplementing the appointment of a Medical Officer with that of a sanitary expert—one who has a practical knowledge of the construction of drainage and other essentials for securing healthy buildings. A few months since there was an outbreak of what is known as one of the "preventable diseases" at the Foreign-office. The case came to the knowledge of the Prime Minister, who immediately asked that the Works Office should make an inspection of the drainage system. The request was complied with, and in due time a report was made that it was efficient and sound. It was therefore thought that the disease must have been contracted in "another place." But only a short time had elapsed when another victim was claimed in the same office. Again the Prime Minister insisted on an inspection, and again the report came forth that all was sound and perfect. But this time

Lord Salisbury was not satisfied, and on his own responsibility called in an independent expert. A fresh examination was made, and very soon it was discovered that "all was not well," but that the whole system of drainage at the Foreign-office was in a deplorable condition. The defects were so glaring that the youngest aspirant to the knowledge of sanitary engineering would have discovered them at once. Thus it is quite certain that the examination made by the department responsible for the condition of our public offices was either of the most perfunctory character, or it was made by someone to whom the principles of good drainage were an "unknown language." It was this episode that led to Dr. Corfield's appointment. But much as we admire this gentleman's abilities, and gladly acknowledge the high position he occupies in the ranks of Public Health Officers, we assert that his appointment is insufficient, and does not meet the requirements of the case. He should be supported by the selection of a thoroughly experienced and practical sanitary engineer, together with two or three first-rate assistants. If these additions were made to the present staff, and a free hand was given for an impartial and drastic inspection of all Government buildings, something like efficiency might be attained. Of course, we would prefer that the Government should bring itself into line with what it demands from others, viz., that its offices should be subject to inspection by the Local Authorities. But as it is not likely at present to do this, we insist that the officers named should be immediately appointed.

We are reminded that the Royal Palaces, too, are under the care of the Office of Works. Here, again, is it essential that expert advice should be sought. If the Department is so careless for the health of civil servants, what confidence can we have in it for looking after the welfare of the Royal Family? On these grounds, also, we urge the necessity for additional officers. Great alterations, we are informed, are contemplated at Buckingham Palace and Windsor Castle. The full extent of the work to be done is not yet finally decided, but it will be sufficient to warrant a complete overhauling of the sanitary condition of both places, and bringing it into line with modern ideas and practice. In all these matters the Government should set a good example to the nation. That the King and the Government should have "privileges" may be needful, but they should not include exemption from a compliance with those precautions necessary for the protection of their officers and servants from the ravages and attacks of "preventable disease."

The L.C.C. Elections.

For many reasons we are gratified at the result of last Saturday's polling for the election of members to the London County Council. It is a clear indication that a municipal spirit has at last been created in the great metropolis, and that the people desire the county to be governed according to its needs, and not the whims and fancies of political partisans. It is folly to think that because a man is Conservative in Imperial politics he is blindly to follow the same lead in regard to local affairs—more especially when the party man who seeks his suffrages is utterly devoid of any policy or idea of the work to be done by a County Councillor. Yet this is what he was asked to do in London, and the reply given is so emphatic that none can misunderstand it. Of all the daily papers, perhaps the *Daily Telegraph* most aptly and truly appraises the position when it says that the one clear "moral to be drawn from the elections is that the electors are in serious earnest in their demand for social reform and municipal progress." No one can say that we have bound ourselves to the Progressive party. We have never hesitated to approve of what we deem right in their proposals, or condemn what we think retrograde or unnecessary. But whilst there may have been some unwise steps taken within the past twelve years, the policy followed by the Council has worked for the improvement of the county and well-being of the people. It is the only body in the country which has seriously tried to grapple with the housing problem: its municipalisation of the tramways has been an emphatic success, for it has given better conditions of employment and wages to the servants, and worked wonders in the development of the system, the Council taking such action as will place it in the very front rank of electric traction within a comparatively short time—and all without adding one penny to the rates, but gaining nearly £50,000 per annum in relief of the same. Then there is the asylum policy, which has revolutionised the treatment of those suffering from the "mind diseased;" its improvement and addition to the open spaces; and many other things, the combination of which is gradually wiping out the stigma once resting upon London as being the least public-spirited and worst governed city in the kingdom. The electors of the County are not unmindful of this change, and their vote given on Saturday is a distinct mandate for a continuance of the policy of progress and reform. We trust also that the last has been seen of importing political spirit into the County Council, and that in future there will be a healthy rivalry displayed by the members in the promotion of the work. Let every question be discussed on its merits, and let it be frankly admitted that public improvements can seldom be carried out without first of all inflicting some cost upon the rates. If the new Council settles down to its work in this spirit, we may look forward to excellent results during the next three years.

The Collapse of the Water Companies' Proposals.

Last Thursday the Local Government Board inquiry into the proposals of the water companies of London for regulating the supply, &c., was brought to an abrupt conclusion. When the inquiry was about to re-open, Mr. Cripps, K.C., volunteered a statement. He defended the action of the companies in making the regulations, contending that they were only carrying out the

recommendations made by Col. Ducat and Mr. Barry in 1895, and endorsed by the more recent Royal Commission. But the Local Authorities did not view them in the same light; and in face of the opposition by these bodies, owing, the companies thought to misapprehensions of the objects aimed at, it was thought to be useless to go on with them, and he asked that the inquiry might not proceed further. It is a pity that this was not done before, for we do not remember any instance where the various Authorities of the metropolis have been so unanimous in their opposition. That this was so was well known before the inquiry opened. It may be, of course, that the objections "were founded on misapprehension," but here, again, the responsibility rests upon the companies. If the new regulations were only to be prospective, it should have been distinctly stated so. But they appeared to many to be open to another interpretation, and capable of inflicting unnecessary and heavy expenditure upon the ratepayers, and the Authorities were perfectly justified in protesting against their adoption. Further than this, sooner or later there will have to be a change in the water supply of London. A "Water Board" or some such body will one day have control over it, and this means that the purchase of the present concerns will have to be made. For this reason alone nothing should be sanctioned that would give the companies an opportunity to increase the already inflated value of their undertakings.

Conditions of Employment in Destructor Works.

We have received a copy of an interesting return obtained by Mr. John McTaggart, superintendent of the Cleansing and Destructor Department of Bradford. Recently the workmen of the department made application for an advance in wages, together with a week's holiday, with full wages, each year. Before giving an answer to this request the Council instructed Mr. McTaggart to obtain information as to the wages paid, hours worked, and holidays given by the principal municipal works in the United Kingdom. This return shows a remarkable difference both in hours worked and wages paid. The stokers at Rochdale only work 44 hours per week, and those of Bristol 45, while those of Darwen are employed for 72 hours. The eight-hour day is in force in Birkenhead, Birmingham, Edinburgh, Leeds, Oldham, and Sheffield. Twenty-seven towns are included in the return, and the average working week is 56·28 hours. In the Bradford destructor department the 48-hour week prevails. The variations in wages are as great as the hours worked. The most remarkable difference is that between Glasgow and Edinburgh. In the former place the wages are 4·75d. to 4·95d. per hour, whilst the latter city pays 7½d. Why there should be a margin of quite 30 per cent. between these two Scottish cities is difficult to understand. In only one town, Derby, is the rate lower than Glasgow, the stokers receiving from 4·64d. to 5·03d. per hour. Twelve towns pay from 5d. to 6d.; seven from 6d. to 7d.; five from 7d. to 8d. The best paid stokers are at Bristol, Edinburgh, Leeds, and Rochdale, and the average rate for the twenty-seven places is 6·12d. Bradford pays 7d. With regard to holidays, none are given in Blackburn, Bury, Colne, Darwen, Hyde, Liverpool, Oldham, Preston, Rochdale, St. Helen's, and Wigan; one day is given at Derby; two days at Birkenhead, Bolton, and Leeds; three days at Manchester, Nelson, and Sheffield; three and a-half at Burnley; four days at Huddersfield and Warrington; five at Birmingham; and five and a-quarter at Glasgow; six at Newcastle-on-Tyne; seven at Bristol and Edinburgh; and eight at Salford. Bradford gives two days to all the employés in the department. From this synopsis of the returns obtained by Mr. McTaggart it will be seen that the case for an advance of wages and a week's holiday is by no means a strong one.

A Good Record at Blackpool.

A few weeks ago we quoted the old saying that "a green Christmas makes a full churchyard," but happily there are no general signs of its fulfilment this year. Thus far the returns for the whole country have been generally satisfactory, but one of the best we have yet seen is from the well-known Lancashire health resort, Blackpool. This report only extends to the first week in February, and shows that out of a provisional population of 51,000 the deaths during the five weeks only totalled 58, against 105 births. A comparison of the two sets of figures perhaps explains the provisional total. Only two visitors died during the period, and when these are discounted the rate works out at 11·72, against 15·62 for the corresponding period of last year, and 18·1 for the 33 great towns. Of the 58 deaths 21 were under five years and thirteen over 65—thus leaving only 21, or an average of four per week, between the ages of 5 and 65. We are not surprised to see it stated by a local paper "that Blackpool's bill of health continues to give every satisfaction at home. That the advantages and benefits of our bracing wintry climate are becoming more and more appreciated abroad no one who frequents the Promenade in the pleasanter portions of the day can doubt."

Precautions against Small-pox.

In connection with the present epidemic of small-pox in Scotland, Sir Henry Littlejohn, Medical Officer of Health for Edinburgh, made the following recommendation to the Town Council. "Looking to the excellent results that followed the increase of the cleansing staff during the plague scare, I beg respectfully to urge upon the Town Council the benefit the city would receive, and more especially the poorer districts, were a similar step ordered while we are daily in expectation of an outbreak of small-pox. Not only were these districts, so to speak, sweetened, and their condition as to cleanliness improved, but the moral effect on the population was most marked, leading to active co-operation

with the sanitary officials." Such a recommendation, coming from such a quarter, might have been expected to be at once acceded to, but strange to say it met with an extraordinary amount of criticism and opposition. It seems to have been thought a reflection on the work of the ordinary cleansing staff, and on the discharge of their duties by the Sanitary Inspectors. The question of cost, though discussed, can hardly have been a serious matter, for only the other day the Town Council voted £1000 to the Public Health Committee to arm them against the threatened outbreak. After a great deal of jangling, the question was remitted to the Cleansing and Lighting Committee with powers. Sir Henry Littlejohn is fully prepared for the possibility of an outbreak. As yet there has only been one case in Edinburgh, but 5000 tubes of lymph have been issued to the medical men of the city, sufficient to inoculate 10,000 persons. The upper and middle classes are readily availing themselves of the opportunity to be re-vaccinated, but those in the poorer districts, who have most need to do so, have been slower to take advantage of the opportunity afforded them. One would hardly have thought that anti-vaccinators would have selected such a time for an assertion of their peculiar tenets, but a case had to be dealt with in the Edinburgh Sheriff Court last week. The accused grounded his objections on the fact that the vaccination of one of his children several years ago had been attended with bad results. The Sheriff attempted to remonstrate with the man on the unreasonableness of his fears, pointing out that with the lymph as now prepared all danger had been removed. The prosecutor explained that this was the sixth child for which the father had been prosecuted. In view of the imminent risk of an epidemic we think the man was most leniently dealt with in being fined only 18s., including costs, for in times of emergency the scruples of the individual must give place to the common weal. In Glasgow the decrease has proved but temporary. The Medical Officer's weekly return last Friday showed an unexpected increase, 130 admissions being recorded, with 90 discharges, and ten deaths. This is an increase of 79 fresh cases over the previous week. It is feared that March will bring with it a renewed activity of the disease.

The Shortening of Shop Hours.

In the House of Lords last week Lord Avebury—who is still better known as Sir John Lubbock—again brought forward the subject of the excessive hours of labour in shops. Last year he introduced a Bill to deal with the question, and it met with a chilling reception from Lord Salisbury; this year he contented himself with asking for the appointment of a Select Committee to inquire into the subject, and to this more limited demand Lord Salisbury could not well refuse to accede. But even in consenting to the proposal the Premier seemed to us to throw a good deal of cold water on it, professing much solicitude for the liberty of the working classes, who were practically without direct representation in Parliament, to make their purchases when it was most convenient. In his anxiety to protect the liberty of the working-class consumers, does he consider the fetters that economic laws impose on the liberty of the poor shop assistants, and the restrictions on their opportunities for enjoyment, exercise, social intercourse, and self-improvement, consequent on their excessively long working hours? Does he consider the effect upon their health that these long hours produce, especially in the case of women? Lord Avebury was able to take most of these points for granted. He had simply to refer to the unanimous resolution of the House of Commons that the hours of labour in shops were excessive, and that legislation was necessary; and to the report of the Committee which sat in 1886, that in many places the hours of labour ranged as high as eighty-four per week, or thirty more than were allowed under the Factory Acts. He also referred to the testimony of Lord Lister in the House last year as to the terrible effects of long hours on health, particularly in the case of women, to which there is absolutely no answer. The shopkeepers of the country are anxious to see the hours of labour shortened, and will readily support any reasonable proposal in this direction. They may well be trusted to be anxious to consult the convenience of their customers, and in any case the consent of the Local Authority, which is required under Lord Avebury's Early Closing Bill, should be sufficient to safeguard the interests of the consumers. It will be noted that in consenting to the appointment of the Select Committee, Lord Salisbury was most careful to guard himself against promising any legislative action consequent on the Committee's report. We earnestly trust, notwithstanding, that the inquiry will not be a merely academic one, but will be the prelude to practical legislation in the interests of the health of a large and important section of the community.

National Health Society.

OFFICIAL TRANSACTIONS.

Training Lectures.—On Monday next, March 11th, a course of lectures on "Public Health and the Duties of Sanitary Inspectors" will be commenced at 53, Berners-street, W., by Henry Kenwood, M.B., L.R.C.P., D.P. The Lectures will be given on Mondays at 4 p.m., and Thursdays 3.30 p.m., and will include several practical demonstrations and inspections of trades, disinfecting stations, &c. The opening lecture deals with "The Duties of the Sanitary Inspector—Objects and Methods of Inspection." The course forms part of the Society's special training for the examination of the Sanitary Inspectors' Examination Board, and for the diploma of the Society.

On Tuesday, March 12th, Dr. Squire will give the first lecture of his course on "Elementary Human Anatomy and Physiology." This course consists of ten lectures, and will be held on Tuesdays at 2 p.m. and Fridays 4 p.m. The lectures form a part of the training for the Society's diploma. The subject of the opening

lecture is "Human Physiology":—The science that treats of the life of man. The essential phenomena of life. Life in its simplest forms—protoplasm—cells. The human body derived from a single cell, and consisting of a commonwealth of cells all working in combination for the common good. Birth, growth, decay, and death. The general structure of the body, and the properties of the elementary tissues.

Examinations in "First Aid" and "Nursing" for the diploma of the Society are to be held at Berners-street during this week. Candidates for the Society's drawing-room certificates will also be examined on these subjects.

Homely Talks.—The following is an extract from a letter received from the secretary of a branch of the Mothers' Union, for whom one of the Society's lady lecturers has been lecturing at the Chapter House, St. Paul's:—"There has been only one verdict on the lectures, both from the ladies who heard them and from our poorer friends, and that is that they were excellent and immensely useful and enjoyable to them all."

Shropshire County Council.—We have received an application from the Technical Education Committee of the Shropshire County Council for Miss Forrester's services for a period of six weeks. Miss Forrester visited Shropshire during the autumn, when she made a most successful tour.

Sanitary Inspectors' Associations.

LONDON.

A general meeting of the members of the Sanitary Inspectors' Association was held on Saturday evening, at Carpenters' Hall, London Wall, E.C. Mr. W. H. Grigg (Fulham), chairman of the Council, presided, and there was a good attendance, including Messrs. T. G. Dee, H. Alexander, Ashdown, Bagshaw, Baxter, J. Jordan, I. Young, Morley, A. G. Duck, Johnson, and Mr. E. Tidman, C.E., the hon. secretary.

It was announced that the annual dinner of the Association, postponed on account of national mourning, is now definitely fixed for the 15th of March, at the Holborn Restaurant. Archdeacon Sinclair will preside, and most of the mayors of the new metropolitan boroughs will attend.

With regard to the uniform question, Mr. James Woonton (Stepney) informed the members that the Stepney Borough Council had decided to abolish all uniforms for Sanitary Inspectors, and had agreed to allow £10 per annum to each officer in lieu thereof.

The Chairman read a paper prepared by Mr. W. J. Addiscott, Chief Inspector of Plymouth, who was prevented by illness from attending, entitled "Some Aspects of the Housing Problem." He said that in dealing with this important social matter, difficulties of all kinds confronted the reformer. Notwithstanding all that had been done by private and public bodies, had we yet accomplished the end aimed at? No. He thought that we were not much nearer the solution of the problem than we were five years ago, and the question was now more pressing than it had ever been before. It was therefore their duty to look round and probe the question deeper still. The fault did not always lie with landlords, because he knew of cases in which the inhabitants of a district preferred to overcrowd old, bad dwellings rather than live in new ones provided at the same rental. A great question was the cost of building houses suitable to meet the wants of the working classes. This was not only caused by the increased price of land, but he did not believe this question would be satisfactorily settled until we get a Land Court established in this country. There was also an increase in the price of building material, an average rise of 25 per cent. having taken place since 1891. The cost of labour, as everyone knew, was also increasing. Rent went up, and this had the tendency to encourage overcrowding, because the higher the rent the less rooms were rented. Artisans and craftsmen earned good wages and were able to look after themselves, but it was the very poor, the unskilled labourer with a precarious living, the impecunious and the thriftless who had large families to bring up, these were the classes which required provision. By many causes, contributing to one end, overcrowding was assisted, and the question had many aspects. There was one important cure which people had in their own hands with which to reform this social evil, viz., temperance. The drinking and drunken habits of the people was a fruitful slum creating cause, and an important cause, of overcrowding. Many families earned good wages, yet owing to drinking habits lived under deplorable conditions. He thought these facts were well known to all his brother Inspectors. Then the general personal habits of the people was also a factor, for some families seemed to sink so low in the scale that if property they occupied was put into thorough repair this week, next week it would be as bad as ever. This was the class which gave the most trouble to Sanitary Authorities. One step would be to diminish the number of public-houses, while the establishment of public wash-houses and drying-places in the heart of the poorest districts would help to improve matters in the homes of the people. Ideal communities could be seen at Port Sunlight and Bournville, and these were a standard to which they could work. But good as cottage colonies are, the careless and thriftless would not avail themselves of such opportunities. Critics often complained of the laxity of Inspectors, but did it ever occur to the critics that they might help the Local Authority by reporting themselves the conditions of which they complained?

An interesting discussion ensued, Messrs. Duck, Alexander, Dee, Tidman, Johnson, Young, Morley, and the Chairman taking part, general agreement being expressed with the views in the paper. A hearty vote of thanks was accorded to the author, and the private conference of members followed.

NATIONAL UNION.

A conference of Sanitary Inspectors, who are members of the North-Western District of National Union of Sanitary Inspectors, was held last Saturday evening in Manchester. Representatives were present from Liverpool, Crewe, Manchester, and other towns and districts. Mr. J. Bland (Urmston) presided. Mr. J. A. Priestley, chief Sanitary Inspector of Nelson, read a paper on "The Old Century and the New from the Sanitary Inspectors' point of View," in which he contended that sanitation was the product of the Victorian era. The early days of the nineteenth century would not be looked back upon as initiating any great changes in the health of the various communities, and although the Public Health Act of 1848 was noteworthy as being the first public recognition by the Legislature that sanitary considerations came within the range and the duties of statesmanship, it was not until the lapse of a quarter of a century in 1872 that the office of Sanitary Inspector was established as a public appointment for both rural and urban districts. At the end of the century the status of the Sanitary Inspector had greatly improved, salaries were higher, the duties were more responsible, their knowledge was greater and their work better appreciated, whilst on the other hand there were many disadvantages under which they had to labour, and there were many improvements which it must be

their aim and endeavour to secure. These included fixity of tenure, superannuation, the extension, amendment, and consolidation of the public health laws, which were of such importance that they called for the attention of the Legislature. A discussion followed.

Public Works.

SEWERAGE.

GREAT SUTTON has decided in favour of a complete sewerage scheme, the cost of which is estimated at £4400.

THE Sedgefield Rural District Council has consulted Messrs. D. Balfour and Son, of London and Newcastle, as to the main sewerage of Trimdon.

AT the monthly meeting of the Belfast Urban District Council the estimated cost of the Greencastle and Whitehouse sewerage scheme was stated to be £5223.

AT the last meeting of the Sewerage Committee of Aberdeen Town Council, the estimate of Messrs Peter Bisset and Sons for the construction of the new storm water culvert in Holburn-street, amounting to £3196, was accepted.

THE Dumfries Town Council has resolved to purchase the estate of Castledykes for £7000 for the proposed sewage works. Castledykes, which is on the extreme south of the burgh, between the foot of the Dock Park and Kingholm, is the site of the old Castle of Dumfries that William the Lion built, and is a picturesque spot. It contains a fine mansion house, situated on an elevated rock overlooking the river.

A LOCAL Government Board inquiry has been held at Lisburn by Mr. P. C. Cowan into a petition by the Lisburn Urban Council to the Local Government Board for a provisional order under the Public Health (Ireland) Acts, 1878 to 1896, to empower the Council to put in force the provisions of the Lands Clauses Acts with respect to the purchase and taking—otherwise than by agreement—of the lands set forth in the petition, for the sanction of a loan of £23,266 12s. 9d. for the purpose of sewerage works, and for £3600 for the purchase of a Town Hall.

AT a meeting of the Royal Scottish Society of Arts, held in Edinburgh last week, Mr. James Thomson, C.E., dealt shortly with the engineering aspect of the septic treatment of sewage, and with the problems presented to engineers of sewage purification works. The septic system was recommended on account of the very small area of ground which it occupied, the minimum amount of attention which its works required, the minimum amount of sludge produced, and the smallest possible amount of smell which an installation of that kind created. He pointed out that the distribution of the sewage over the filtering area was one of the greatest difficulties to be met with, and a number of distributors (including one of Mr. Thomson's own design) were described. Mr. Thomson was in favour of closed septic tanks and open bacteria beds for small communities, but for large communities he was in favour of both open septic tanks and open bacteria beds. He was in favour of continuous filtration in preference to intermittent filtration for small communities, and for large communities of intermittent filtration. The sewage purification works in connection with the proposed lunatic asylum at Bangor for the Edinburgh Parish Council were referred to, and it was pointed out that there it was intended to dispense with automatic gearing, and to have an attendant to actuate the valves when required. In conclusion, the engineer referred to the cost of installation of this system in various parts of the country.

THE St. Columb ratepayers have decided to recommend the Rural District Council to adopt Mr. Worth's scheme of sewage disposal for the district.

ACCORDING to the latest news to hand from Sydney, N.S.W., the Water and Sewerage Board has approved the recommendations of the Engineer for extension to the sewerage reticulation at North Sydney, near Cammeray Park, at an estimated cost of £1600; sewer, Bondi-road, Bondi, to cost £600; and extension to the sewerage reticulation of Randwick, to cost £1400.

AT the last quarterly meeting of the Armagh County Council a letter was read from the Lurgan Rural Council enclosing for adoption by the County Council a resolution calling upon the Government to take some steps to make the present Bann drainage system effective in preventing flooding of the districts affected. Accordingly a notice of motion in support of same was handed in.

AT the last meeting of the Tredegar Council Messrs. Beasley, Sons, and Nichols, engineers, were appointed to report upon the best system for disposing of the sewage of the district. The Council was impressed with the urgent necessity of destroying the refuse, as large tips had accumulated in close proximity to dwellings. It was reported that persistent overcrowding had disappeared, and the insanitary dwellings were gradually decreasing.

PROGRESS is being made with the water supply and sewage disposal scheme at Carlton. At Notton a spring from which water is used for domestic purposes is being polluted by sewage from Roystone, and the water supply and sewage disposal at Wooley Colliery is unsatisfactory. The Clerk to the Barnsley Council reports that the negotiations with regard to the Carlton sewage scheme have been completed, and he has been instructed to write respecting the other matters mentioned.

MR. DONALD CAMERON, City Surveyor, Exeter, in his last report states that the work of constructing the main intercepting sewer is now finished, with the exception of two lengths. With regard to the St. Thomas sewage, the Local Government Board has written that it raises no objection to the septic system "as an experimental process, for which the Town Council take entire responsibility," but considers that the works should be designed on a basis of a minimum dry-weather flow of 230,000 gallons a day, instead of 170,000 gallons as proposed, and amended plans are being prepared accordingly.

MR. NORTH, A.M. Inst. C.E., the Inspector of the Local Government Board, visited Morpeth last week to inspect the site at the Low Stanners proposed for the bacterial tanks, and the land in the Parish Haugh for the sewage disposal works. An application was also made at the County-court, Morpeth, on Tuesday, before Judge Greenwell, for a further extension of time for the carrying out of the works to prevent the pollution of the river Wansbeck, designed by Messrs. D. Balfour and Son, of London and Newcastle, when it was agreed that the Urban Council should come before the Court again in April, to have a Peremptory Order made.

COLONEL W. R. SLACKE, R.E., recently held an inquiry at the Urban District Council offices, Newhaven, into the application of the Council to borrow £1143 for sewerage and street improvements. The Clerk explained that the loan was required owing the large growth of the town, which rendered it absolutely necessary that the main sewer should be extended and another portion altered so that the low-lying sewers through the ship yard and Chapel-street might be relieved of the whole of the sewage from the higher part of the town. Mr. F. J. Rayner, the Town Surveyor, then explained the proposed scheme of sewerage and the different street works, and there being no opposition the inquiry terminated.

The Romily Urban District Council has decided to apply for sanction to borrow £6480 for land required for sewage disposal, and £470 for tramway purposes.

A Local Government Board inquiry was held at Newcastle-under-Lyme last week by Mr. H. Percy Boulnois, M.I.C.E., and Mr. L. W. Darra Mair, M.D., with respect to an application by the Town Council for sanction to a loan of £15,000 for the purpose of the reconstruction of the main outfall sewer and sewage disposal works. The scheme has been prepared by Messrs. Willcox and Raikes, civil engineers, of Birmingham, and comprised a new main outfall sewer and the construction of 6500 yards of bacteria beds, together with the diversion of brook course as well as laying out certain areas of land for dealing with storm water. Many witnesses were called, and the Inspectors visited the site of the proposed works.

WATER.

The Brixworth Rural District Council has decided to spend £800 in improving the water supply of Great Creaton.

The Hastings Town Council has decided to lay new water mains in several of the principal thoroughfares in the town at a cost of £2623.

The Toronto and Lake Erie ports, on both sides, are threatened with a great loss, owing to the lowering of the lake level by the drawing off of the water in the Niagara River. A great volume of water is now utilised for furnishing electrical energy, and this is the cause of the shrinkage. The Ontario Surveyors' Association are discussing the remedy and improvements in the supply, which, if adopted, will cost 2,000,000 dols.

At a special meeting of the Ripley Urban District Council, Dr. Hooper, who presided, moved: "That this Council petition against and do oppose the Ilkeston and Heanor Water Bill, and take all necessary legal and other steps in the matter, and do obtain all clerical, legal, and other assistance for the purpose." The ground on which they would oppose the Bill was that the streets of Ripley would be cut up, and the mains interfered with to a great extent. They should have a clause inserted whereby they might get compensation for the streets being taken up. The resolution was carried unanimously.

The usual fortnightly return of the Edinburgh Water Board just issued shows that the total quantity of water in the reservoirs on the 26th ult. was 2,655,195,000 gallons, or a decrease of 10,971,000 gallons as compared with the quantity stored on the 12th inst. During the previous fourteen days the average delivery in the city was 16,456,000 gallons—equal to 39·17 gallons per head per day to a population of 420,000. The rainfall at Glencorse from the 1st to the 26th inst. was 3·10in., and at Gladhouse 3·51in.; while for the corresponding periods last year the figures were :—Glencorse, 9·00in.; Gladhouse, 8·25in.; and in 1899—Glencorse, 7·70in.; Gladhouse, 6·65in.

The Wisbech Waterworks Company has a Bill before Parliament intended to secure an extension of its powers. The Wisbech Corporation and March Urban Council have resolved to petition against the Bill. The Town Council declares that its opposition is simply designed to protect the interests of the ratepayers. The Waterworks Company, on the other hand, alleges sinister designs on the property of the company—in fact, they affirm that the Corporation desire to buy them out, and that their opposition is prompted by the hope of thus more easily attaining their object. It is difficult to determine between the two bodies, but the ratepayers are to express themselves by a poll of the borough. The situation is an interesting one, and developments will be awaited with interest.

At Millom last week a gathering of ratepayers and owners of property was held to take into consideration the Bill being promoted in Parliament by the Barrow Corporation to enable them to take water from the river Duddon. The meeting considered that the Bill would be detrimental to the interests of Millom as a town and port, seeing that it would interfere with the scour in the Duddon, and so prevent sewage from being taken to sea, and also that navigation would be endangered. It was decided to oppose the Bill, the cost to be charged to the rates.

At the last monthly meeting of the Sleaford Rural District Council Mr. J. Clare, C.E., made a special report as to the inadequate water supply of Digby, and stated that a further outbreak of typhoid fever had occurred through drinking water from a polluted well. Half of the houses were without a supply, and the wells supplying the remainder contained water of a questionable quality. Dr. Giles had analysed the water, and found it contaminated with sewage matter. It was resolved that the well in question be closed, and that Mr. Clare prepare a plan and estimate for a proper water supply for the parish, the Parish Council having already communicated with the Local Government Board on the subject.

At a recent meeting of the Hunslet Rural District Council, the principal subject discussed was the alleged presence of lead in the water supply to Middleton. The question had been raised by Dr. Buck in his annual report, which stated that the Middleton water, supplied from Morley, still acts on the lead when standing in the pipes overnight. Various samples had been taken during the year, and no improvement had been perceptible, and he was of opinion that the matter should be brought before the Morley Corporation, with a view to its abatement. After discussion, it was agreed that the inhabitants of the district be informed that it was not desirable to use the water in the morning without first opening the tap and letting it run some time. The chairman said they must prepare themselves for a considerable waste of water.

A matter of considerable importance to the Tees-side boroughs came before the Middlesbrough General Purposes Committee last week. The Darlington Corporation proposes, it appears, to increase its water supply from the Tees, and that can only be done by appropriating a very large proportion of the compensation water which the Tees Valley Water Board have to discharge into the river. When it is remembered that it was the Darlington Corporations who compelled the Water Board to discharge this compensation water from the Balder Reservoir into the river, its present action, in the absence of explanation, seems somewhat strange. A Sub-committee has been appointed by the General Purposes Committee to consider the question, and there can be no doubt that the scheme of the Darlington Corporation will be strenuously opposed if found to be injurious to the river and the towns upon its lower reaches.

LIGHTING.

The Electric Light Company have broken up the Barnet roads in order to lay their cables, and have left them in such a state that the Council declines to give the company a certificate that they have left the roads in a good condition.

At the last meeting of the Bridgwater Town Council a communication was read from the Local Government Board respecting the application made last year by the Town Council for sanction to borrow £20,000 for purposes of electric light, and stating that unless the Town Council passed a resolution renewing the application, the Board proposed to regard the original application as withdrawn.

An extension of the Conway gasworks is to be undertaken, at a cost of £8000.

The net profit of the Oxford Electric Light Company for the past year ending December 31st, 1900, is stated to be £2905 11s. 10d.

A Board of Trade inquiry was held at Carnarvon last week with reference to the Provisional Order sought for the lighting of the town by electricity.

A Local Government Board inquiry has been held at Derby, relative to proposed loans of £35,850 for electric lighting purposes, and £1785 for works of street improvement.

The annual meeting of the Exeter Gas Light and Coke Company took place last week. The report, which was of a very satisfactory character, was adopted, and the usual dividends were declared.

We understand that the Municipality of the City of Bombay has granted a concession to Mr. W. Gentry Bingham, on behalf of the British Pioneer Electric Light and Power Company of India, for the electric lighting of the city, and for the electrical equipment of the existing 60 miles of horse tramways, and that a group of city financiers has guaranteed the necessary funds for that purpose, amounting to about £2,000,000 sterling.

The Lichfield District Council has decided that an application be made to the Local Government Board for the issue of an Order investing them with the powers of the first paragraph of Section 161 of the Public Health Act, 1875, with a view to making the necessary provision for the lighting of the portion of the main road in the parishes of Brereton and Colton, which leads from the town of Rugeley to the Rugeley Junction Railway Station, and that the Local Government Board be further requested to order the expenses of lighting the same to be special expenses chargeable upon the said parishes of Brereton and Colton.

The Examiners having reported that in the case of the South Yorkshire Electric Power Bill the Standing Orders had not been complied with, the matter last week came under the consideration of the Standing Orders Committee of the House of Commons. The Committee having deliberated in private, the parliamentary agent for the promoters was called in, and Mr. Halsey, the chairman, announced the decision of the Committee. He said they had decided to allow the Standing Orders to be dispensed with on the condition that the proposed exemption of the undertaking from the provisions of Section 81 of the Electric Lighting Act of 1899 be struck out of the Bill.

In the half-yearly report of the Cheltenham Gas Company recently submitted, the directors recommended the payment of the maximum statutory dividend of 5 per cent. per annum upon the paid-up consolidated ordinary stock. The operations of the company for the year have been satisfactory. The gas consumed shows an increase of upwards of 24,000,000 cubic feet, as compared with that of the previous year, and the number of gas consumers, both on the ordinary and coin meter systems, shows the average yearly increase. The values of residual products have during the greater portion of the year been well maintained. The sale by auction of £5000 consolidated ordinary stock realised a premium of £1315 10s.; and to provide for the further requirements of the company, the directors propose to offer another sum of £5000 of such stock. The revenue account gives a total expenditure of £55,915, of which £44,906 is for the manufacture of gas, £4775 for the distribution of gas, £1979 for public lamps, £1284 for rates and taxes, and £2677 management expenses. The receipts were £51,110 by the sale of gas, meter, and stove rents, £18,516 by residual products, and £1142 for other items, making a total of £70,770, and a profit balance of £14,854.

The London County Council has agreed to lend the Battersea Borough Council £10,600 for electric light installation.

The Hendon Urban District Council contemplates lighting its district by electricity under the Order obtained some time ago.

The Eastwood Urban District Council has unanimously decided to oppose the Derbyshire and Notts Electric Power Bill.

The directors of the British Gas Light Company, Limited, propose to recommend a dividend at the rate of 10 per cent. per annum for the half-year ended December 31st last.

The Lodging-house Sub-committee of Aberdeen Town Council met last Friday, and had under consideration the question of the lighting of the Corporation lodging-house. When the building was erected it was fitted with an installation of the electric light, but this system of illumination is considered to be far too costly for such an institution, the annual bill running to about £200. It was therefore resolved to request the city architect to submit an estimate of the cost of providing gas fittings, with a view to introducing gas instead of electric light. It was also decided, in order to the better conduct of the house, to empower the superintendent to adhere more rigidly to the rules as originally laid down by the Town Council.

The directors of the Abingdon Gas Light and Coke Company, Limited, have just issued their report for the year ending December 31st last. The accounts show, after providing for interest on the debenture bonds and the interim dividend paid in October last, a balance of £1402 17s. 3d. The quantity of gas sold during the year amounted to 19,054,600 cubic feet, being an increase of 1,609,000ft. on that of the previous year. During the past year the construction of the regenerative furnaces have been completed, and the directors were glad to report that they had proved very satisfactory in their working. The saving effected by the installation of these furnaces obviated the necessity of raising the price of gas, which the increased cost of coal would have otherwise rendered compulsory.

Last week a resolution was unanimously passed by a meeting of owners and ratepayers of Cleckheaton, held at the Town Hall, authorising the District Council to oppose in Parliament the Bill which is being jointly promoted by the Heckmondwike and Liversedge Councils for the acquisition of the undertaking of the Heckmondwike Gas Company. The proposal of the Bill is to authorise the joint boards to supply gas throughout Heckmondwike and Liversedge, two portions of which latter—namely, Moorbottom and Marsh—are within the statutory gas area of Cleckheaton. In reply to a question, Mr. W. H. Clough, the Council's solicitor, read correspondence showing that a request for a protective clause had not been satisfactorily met, and said that the Council, therefore, felt bound to proceed to opposition to secure their rights.

A Board of Trade inquiry by Sir Courtenay Boyle was opened at the Westminster Town Hall last Friday into the question whether electric lighting companies and Local Authorities supplying electricity can raise the current from 100 volts to 200 volts without the consent of the consumer. In 1896 the Board of Trade made regulations for ensuring a proper and sufficient supply of energy. These regulations contained a proviso:—"That no change should be made in the pressure of the supply to any premises which, at the date of these regulations, were supplied with energy by the undertakers except with the consent of the consumer." The alteration applied for by the Westminster Electric Company (which has led to this inquiry) was to substitute for the words "with the consent of the consumer," the words:—"On such terms and conditions as may be agreed

upon between the undertakers and the consumer, or, failing agreement, as may be settled by an arbitrator appointed by the Board of Trade." The inquiry was adjourned until to-day.

GENERAL.

THE Leicester Council proposes purchasing and erecting new public baths at the municipal offices.

THE Local Government Board has sanctioned a loan of £6000 for the enlargement of the hospital at Keycol Hill.

THE Leamington Town Council has decided to provide a Horsfall refuse destructor and other necessary works for the destruction of the town refuse.

THE Local Government Board has sanctioned the borrowing by the Chelmsford Town Council of £4750 for the erection of an infectious diseases hospital.

HASTINGS has had a Special Committee formed to find out the best means for promoting housing reform in the town. At the last meeting of this body one member asserted that there were twenty-eight persons living in a four-roomed house, and that this is but a sample of what prevails in the poorer parts of the town.

AT Hanley, last Thursday, the Corporation—for whom Mr. A. Challinor, Town Clerk, appeared—obtained orders from the borough magistrates, under the Housing of the Working Classes Act, 1890, for the closing of four dwelling-houses which were certified by the Medical Officer to be in an insanitary condition and unfit for human habitation.

IN the course of an inquiry before the Magistrate at Romford, into the death of a child, it came out in evidence that nine persons slept in one room—six in one bed and three in another. The state of the house was "simply filthy." The family was too poor to live in a better house, and yet the "mother" could send to the public-house six times a day for beer.

A CHANGE is to be made in the collection of offensive refuse from tradesmen in Woolwich. Hitherto the Local Authority has removed such refuse free of cost; but after the present month it is proposed to charge a small sum for each receptacle collected. At the last meeting of the Council three suggested charges were put forth, viz., 3d., 4¾d., and 6d., but eventually the whole matter was referred back to the Committee bringing up the report.

THE Markets Committee of the Manchester City Council has issued a report in which an account is given of the unwholesome food condemned and destroyed in the city under the Public Health Act, 1875, during last year. This includes 179,598 lb. of meat, 146,040 lb. of fish, and quantities of poultry and game, fruit, and vegetables. Nearly the whole, it is stated, was surrendered by the trade after being condemned by the Inspectors. There were seven prosecutions under the Public Health Act, and in each instance a fine was imposed.

AT the last meeting of the Common Council of the City of London, the Joint Sanitary and Officers and Clerks' Committee brought up a report with regard to the vacant offices of Medical Officer of Health and Public Analyst, held by the late Dr. Sedgwick Saunders. It was resolved that the Medical Officer should devote the whole of his time to the work, and receive a salary of £1000 per annum, and that the candidates were to be not less than thirty-five or more than fifty. In regard to the Public Analyst, it was decided that his salary should be £200 (minimum), or at the rate of 10s. per sample analysed. The Committee were empowered to select three candidates for each position for submission to the Court.

THE Billericay Rural District Council has decided to apply to the Local Government Board for sanction to borrow £1000 for tar-paving footpaths in Shenfield and South Weald parishes.

COL. LUARD, R.E., held an inquiry at Ilford last week in reference to an application of the Ilford Urban Council to borrow £1000 for fire hydrants, £500 for a manual fire engine, fire escape, and other accessories, and £350 for wagons for scavenging purposes. There was no opposition.

AT a recent meeting of the Farsley District Council, proposals were submitted for building about eighty "back-to-back houses." After an animated and lengthy discussion the plans were rejected. We are surprised to know that some of the plans were submitted on behalf of one who formerly occupied the position of Medical Officer of Health.

THE Manchester Port Sanitary Authority on Monday last decided to take special precautions against the spread of plague. It was reported that since 1894 the plague had spread generally along the lines of commerce; that it is to be found along a belt of at least 200 miles in South America, and that its presence is traced in India, the Cape of Good Hope, and Singapore.

THE Special Committee of the Salford Town Council, appointed to consider whether any member of the Council had contravened the Municipal Corporation Act by accepting directly or indirectly corporation contracts, reported on Monday that in its unanimous opinion three councillors had shown a lack of scrupulous regard for their obligations as members of the Council. The amounts involved in all the cases reported upon were small.

THE Governors of the Peabody Donation Fund point out in their thirty-sixth annual report that the trusts are now under Royal Charter. The net gain of the year from rents and interest had been £36,197 8s. 7d., the total fund up to the 31st December last amounting to £1,327,548 17s. 1d. By the end of the year the Governors had provided for the artisan and labouring poor of London 11,439 rooms, besides bath-rooms, laundries, and lavatories. The rooms comprised 5159 separate dwellings, viz., 100 of four rooms, 1770 of three rooms, 2440 of two rooms, and 849 of one room. The average weekly earnings of the head of each family in residence was £1 3s. 1¼d., and the average rent of each room 2s. 3¼d.; the rent in all cases including the free use of water, laundries, sculleries, and bath-rooms.

THE Barry District Council's refuse destructor is now completed, and was opened on Wednesday, the 6th inst. It is the first of the kind in Wales, and was constructed from plans prepared by the Surveyor to the Council (Mr. J. C. Pardoe), and built by Messrs. Lloyd and Tape, Barry Dock, at a total cost of £8000. The buildings abut on the Barry-road, Cadoxton, at the foot of Crogan Hill, the area of the site being 1 acre 1 rood 25 perches. From Barry-road there is an inclined roadway, from the top of which the refuse is tipped into the cells, of which there are two, capable of burning 30 tons of house refuse to a hard innocuous clinker per day. The cells are adapted for the destruction of all kinds of town and market refuse, including condemned meat, fish, infected mattresses, &c. The boiler is suitable for a daily working pressure of 150 lb. to the square inch. The engine room contains one horizontal high-pressure engine (non-condensing), with a cylinder 10in. diameter for a stroke of 20in. There is one high-pressure fan, with steel shaft and protected bearings. The whole of the floor of the building is covered with granite paving. The chimney stack was constructed by Mr. J. Prout, contractor, Barry Dock, and is 150ft. high, with detached fire-clay brick lining, 5ft. internal diameter, carried to a height of 125ft., and close fire-clay lining to the top. The buildings will be lighted by electricity.

A Local Government Board inquiry has been held at Bootle with reference to the application of the Town Council for power to borrow £8150 for additions and alterations to the Town Hall and offices, and £7000 for sanitary improvements.

The foundation stone of a new lunatic asylum for the county of Middlesex was laid on Tuesday in last week, by the Chairman of the Asylum Committee. The site of the new building is 440 acres in extent, and was purchased at a cost of £45,000. It is situated just outside St. Albans, at Napsbury. The estimated cost of the buildings alone is £358,100.

The continued prevalence of measles in Liverpool was referred to by Dr. Hope at the meeting of the Liverpool Health Committee last Thursday, and it was stated that the malady did not show signs of decreasing. Thirty-one deaths were registered last week. A considerable number of schools had been closed. The disease was confined practically to the north, centre, and east of the town. At a meeting of the Toxteth Park Guardians, on Thursday, it was agreed to accede to the request of the city Medical Officer of Health, and receive cases of measles in their hospital.

The Lord Provost of Glasgow last Saturday stated that exaggerated and ludicrous reports of the small-pox epidemic had been published on the Continent which might seriously threaten the prospects of the International Exhibition to be opened in the city in May. He hoped the Press would in referring to the outbreak not go beyond the real facts. Daily bulletins would be resumed, and large medical and sanitary staffs had been engaged to persuade people to be re-vaccinated. Monday's bulletin stated that since Saturday 39 cases had been admitted to hospital, 13 had died, and 54 patients had been discharged as cured, leaving 370 still in hospital.

On the 7th March, 1892, the Local Government Board of Scotland found it necessary to issue a circular directing attention to the necessity of care in the removal of sick persons to the poorhouse, and they have reason to hope that benefit has resulted. But cases have lately occurred which appear to indicate the necessity of an addition to the form of medical certificate, with the object of reminding the certifying Medical Officer of points for the consideration of which he is responsible, and which the Board regard as of special importance. Copies of the form as now revised have been issued, and the expediency of providing modern ambulance carriages for the use of at least all the larger poorhouses is suggested. The removing officer or other official in charge should be authorised to delay, or abstain from, removal if the condition of the patient appears to be alarming, until further advice is obtained.

PERSONAL.

Dr. Brodie has been reappointed Medical Officer of Health for Battle.

Dr. Kennedy has been reappointed Medical Officer of Health for Beaconsfield.

Mr. G. F. Metzger has been appointed Chief Electrical Engineer to the Manchester City Council.

Dr. A. J. B. Adams, of Barnes, has been appointed Medical Officer of the Children's Homes, Barnes.

Dr. J. Dixon Adams has been unanimously reappointed Medical Officer for Yeovil for the ensuing year.

Dr. Trotter has been reappointed Medical Officer of Health for Honley, and Mr. Joseph Ranfield has been reappointed Sanitary Inspector, at salaries of £25 and £30 per annum respectively.

The Local Government Board has sanctioned the reappointment of Mr. Richard Hoyle as Sanitary Inspector for Haslingdon.

Dr. Bond and Mr. W. Williams have been reappointed Medical Officer of Health and Inspector of Nuisances respectively for Chepstow.

Mr. W. E. A. Hay has been unanimously reappointed Medical Officer of Health and Mr. J. W. S. Bartlett Inspector of Nuisances for Bridport.

Mr. D. Balfour, jun., of Messrs. D. Balfour and Son, of London and Newcastle, has been elected a Member of the Institution of Civil Engineers.

Dr. E. J. Sheppard, Public Vaccinator for the Clifton district of the Bristol union, has been awarded for the seventh consecutive time the Government grant for efficient vaccination.

The salary of Mr. M. W. Wilkins, as Town Clerk for Battersea, has been increased from £500 to £760, with the proviso that all sums be received for acting as returning officer, &c., should be paid into the borough funds.

OBITUARY.

MR. F. SIMS, OF DOVER.

We record with regret the death of Mr. F. Sims, the Dover Chief Sanitary Inspector. Mr. Sims has been off duty for several weeks, and his advanced age, coupled with the recent death of his only son, were circumstances against his recovery. He has lain in a critical condition for several days, and passed away at ten o'clock on Wednesday night in last week. Mr. Sims has been the Sanitary Inspector of the Town Council for about forty years, and he has done his duty during that period with good judgment, and with sufficient energy for practical purposes. For a long time he worked single-handed, but for several years past he has been relieved by the able assistance of Mr. Pine, and only a few days before his death another officer, Mr. Pryor, was appointed for special duties connected with the port and the drainage. His death will lead to a re-arrangement of duties, but probably not to the appointment of another official at the present time.

FORTHCOMING MEETINGS.

March.

Friday 8th.—The Sanitary Institute—Lecture to Sanitary Officers at 7 p.m. "Sanitary Building Construction and Planning: Soil and Local Physical Conditions," by Professor T. Roger Smith, F.R.I.B.A.

Friday 8th.—The Sanitary Institute—Examinations in Practical Sanitary Science and for Inspectors of Nuisances, Edinburgh.

Saturday 9th.—The Sanitary Institute—Examinations in Practical Sanitary Science and for Inspectors of Nuisances, Edinburgh.

Saturday 9th.—Inspection and Demonstration at Beddington Sewage Farm, at 3 p.m., conducted by T. Walker, Borough Engineer and Surveyor, Croydon.

Saturday 9th.—Lecture to School Teachers, Bedford College.

Monday 11th.—The Sanitary Institute—Lecture to Sanitary Officers at 7 p.m. "Ventilation, Lighting, and Warming," by W. C. Tyndale, M. Inst. C.E.

Tuesday 12th.—The Sanitary Institute—Lecture to Sanitary Officers at 7 p.m. "Calculations, Measurements, and Plans and Sections," by W. C. Tyndale, M. Inst. C.E.

Wednesday 13th.—The Sanitary Institute—Sessional Meeting at 8 p.m. Discussion on "Ventilation: Success and Failures of the Methods at Present in Use," by Christopher Childs, M.A., M.D., D.P.H.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," THE SANITARY RECORD, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2108.—TRADE REFUSE: MEANING OF.—"A.I.S.E." writes:—"Under Sec. 42 of the Public Health Act, 1875, the Local Authority undertakes the removal of house refuse. Would you advise whether this would include the refuse from a large restaurant, and also from wholesale and retail grocery, drapery, and other businesses? Will you also please give me a definition of trade refuse?"

Answer.—We are of opinion that the refuse from each class of premises referred to is trade refuse. There is no statutory definition of the term "trade refuse." Local Authorities can only be required to remove such refuse as is ordinarily found or created in a house, using the expression "house" in the restricted sense of a "dwelling-house." They are not bound to remove dust and ashes, the exclusive produce of factories, mills, or workshops, or clinker from furnaces, or refuse of a similar kind.

2109.—WATER SUPPLY: TESTS FOR HARDNESS: BOOKS ON.—"H. J." writes:—"Can you recommend me a book on water supply, and as to the different methods of detecting hard water, and the means to be taken for softening same?"

Answer.—Rideal's "Water and its Purification," price 7s. 6d., is an excellent book for the use, as indicated by its sub-title, of "Local Authorities, Sanitary Officers, and others interested in water supply." The methods in use for the softening of water are described. For those who do not possess a knowledge of chemistry, Danchell's "Tests for the Detection of Impurities in Water," &c., may be used. These tests are described in the *brochure*, "Water: Its Impurities and Purification," price 6d., published by the London and General Water Purifying Company, Limited. Either of the books may be obtained from the offices of this journal.

2110.—ELECTRIC LIGHT MAINS: PROXIMITY TO IRON GAS MAINS.—"Surveyor" writes:—"An electric lighting company are about to lay their mains in the streets within a foot of the gas mains. The Council think this is very undesirable, on account of leakage, &c., of the electric mains, and that the latter ought to be much further from the gas mains. Will you inform me if there is any specified distance at which electric mains should be laid from the gas mains with safety?"

Answer.—There is no distance prescribed by the Electric Lighting Acts or Orders issued by the Board of Trade under the Acts, in respect to which electric light mains shall be laid from gas or water mains. If the electric light mains are properly laid in earthenware conduits imperviously jointed, and the copper strips properly insulated by covering, no danger may be apprehended from the mains being laid within one foot of each other.

2111.—COMPO-BOARD: MANUFACTURERS OF.—"Architect" writes:—"Can you oblige by giving me the name and address of the material known and described as compo-board, and referred to in your issue of November 9th, page 418?"

Answer.—The British Compo-Board Company, 18, Brescoe-street, Golden-lane, London, E.C. We advise all architects to obtain a sample of the material.

2112.—INSANITARY PREMISES: POWER OF DEMOLITION.—"Surveyor" writes:—"Kindly advise on the following:—A. built a house about thirty years ago. By the terms of his lease he has an 8ft. right of way outside his garden wall. B., who is now dead, obtained verbal permission from A. to build a hut, to which A.'s garden wall forms the back wall of the hut, which was intended for human habitation for about seven years. On several occasions, A. made a verbal request for the removal of the hut, but being on friendly terms with B.'s relatives, did not press on them. The hut has, however, now been occupied for about twenty-five years. A. is building a stable at the end of his garden, the drain of which must be laid underneath the floor of the hut. Query:—(1) Can A. compel the removal of the hut now? (2) If not, can he claim to lay his drain underneath the floor of the hut, which will be a separate drain for the stable alone? (3) In case the hut cannot be removed, and A. making use of the stable, will you advise which building will have to be demolished, the hut or the stable; that is, if the Medical Officer of Health will condemn the hut as being unfit for human habitation, on account of being too near the stable?"

Answer.—(1) No. (2) Not without paying compensation, even assuming that by the terms of his lease he is entitled to lay a drain in the original right of way. (3) Without the facts as to the sanitary condition of the two buildings, it is quite impossible for us to advise. We do not see, however, under what circumstances the Medical Officer of Health can condemn the new stable so as to secure its demolition.

2113.—HOUSE DRAINS: VELOCITY FOR SELF-CLEANSING.—"H. J." writes:—"The drain of a house is 75ft. long, and it is only possible to get 14½in. in that length. With such a fall, should the drain be of 6in. or 4in. diameter? What velocity per minute would each size have, and if a 4in. drain was laid, would it be self-cleansing? There are three water-closets, one bath, one lavatory, and one scullery sink discharging into it, and in any case they will be only 4in. in diameter. The diameter of drain from sewer to, and including that of the interceptor, is 6in., the taper-pipe being the first one outside the manhole?"

Answer.—The gradient or rate of inclination of a drain laid with a fall of 14½in. in 75ft. is 1 in 62·07. It is required to know whether either a 6in. or a 4in. pipe drain laid at this gradient would be self-cleansing, and to determine this it is necessary to ascertain what will be the velocity of flow. This may be ascertained when the gradient and diameter of pipe is known from Eytelwein's formula, viz.:—

$V = 55 \sqrt{R \times 2H}$, where

V = the velocity in feet per minute.

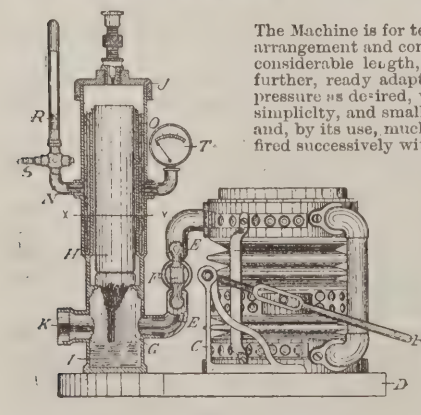
R = the hydraulic mean depth of the pipe in feet, which in those running full or half full is found by dividing the diameter by 4.

H = the fall in feet per minute.

Or the velocity may be found from tables such as Crimp's

RAVENOR'S PATENT DRAIN TESTER

No. 11222.



The Machine is for testing drains and soil pipes by means of smoke and air pressure, and has for its object the arrangement and construction of an apparatus with which Smoke Rockets can be used very effectively in drains of considerable length, without danger of explosion of unconsumed gases emitted from the previous Rocket, and further, ready adaptability is secured for testing with air and smoke separately or combined, at high or low pressure as desired, viz., from ½ oz. to 10 lb. or more. A great feature of the apparatus is its extreme portability, simplicity, and small size compared with existing machines; at the same time its capacity is very considerable, and, by its use, much time and expense is saved in testing long lengths of drains, as a number of Rockets can be fired successively without disturbing the connection with the drain, and without fear of explosion. At the bottom of the smoke chamber, Fig. G, will be found a small receptacle, Fig. I, for containing water, which will catch and extinguish any sparks or incandescent material that may be emitted by the Rocket during combustion, also fresh Rockets may be inserted by simply removing the brass cap, Fig. J, at the top of the cylinder.

This machine is undoubtedly the best, simplest, and most complete of its kind, and will be found to contain all the advantages claimed for it by the inventor.

Water Supply. Rodda. 5s.

"Tables and Diagrams for Use in Designing Sewers and Water-mains." (Price 10s. 6d.) As we have already shown, the rate of inclination of the proposed drain is 1 in 62. For a 4in. pipe Crimp's tables show that the velocity would be 180ft. per minute, or 3ft. per second, and for a 6in. pipe the velocity would be 236ft. per minute, or 3·93ft. per second. Now the least velocity which house drains should have to ensure their being self-cleansing is 3ft. per second, and as this is obtained in the case of both the 4in. and the 6in. pipes if laid at the gradient proposed, the querist may safely put down pipes of either diameter.

2114.—Housing of the Working Classes Act, 1890: Owner.—"W.H.O." writes:—"In Section 32, Part II., of the above Act, Local Authorities are directed to take proceedings before justices for the closing of dwelling-houses unfit for human habitation, but in the definition of owner in Sec. 29, the term includes all lessees or mortgagees of any premises required to be dealt with under this part of this Act, except persons holding or entitled to the rents and profits of such premises for a term of years, of which twenty-one years do not remain unexpired. Am I to understand by this that a closing order cannot be obtained against an owner whose lease has less than twenty-one years to run?"

Answer.—The interpretation to be placed upon the section is that a closing order cannot be obtained against a lessee whose lease expires within twenty-one years, but against the superior landlord. The Local Authority in dealing with houses which are unfit for human habitation have the option of taking proceedings under the Public Health Act or under the Housing of the Working Classes Act in cases where a house can be rendered fit for human habitation. When proceedings are taken under the former Act, the "owner" is the person defined as such in Sec. 4 of the Act of 1875. But when it is desired to obtain a demolition order proceedings should be taken under the Housing of the Working Classes Act, 1890.

2115.—New Building: Approval of by Local Authority Entails no Liability.—"Plymouth" writes:—"(1) The owner of a yard has blocked up some windows of a house belonging to another owner, which windows overlooked his yard. Can he legally do so, as it may be said that the health of the occupants of the house is endangered from want of light and ventilation? (2) The owner of the house whose windows are blocked has sent in a plan for rebuilding his house and bringing it forward to line of adjoining buildings, and this has been approved by the Rural District Council. It is stated that the land on which he proposes to bring forward his house belongs to the public, and the Council have no right to allow him to do so. The Parish Council acquiesce in the house being brought forward. Can the person who objects to the house being brought forward hold either the Rural or the Parish Council liable if this be built upon?"

Answer.—We doubt whether the Council would succeed in an action against the owner of the yard for blocking up the windows of his neighbour. The matter is a personal one, and the powers of the Act should not be utilised to remedy private grievances and quarrels. (2) Unless the land on which the proposed new house is to be built is indubitably a part of the highway; the person who objects has no remedy. The approval of the plan by the Authority in no wise renders them liable to any action at the instance of a person aggrieved.

2116.—Nuisance from Defective Drain: Written Application by Inspector.—"S. J." writes:—"I visited certain premises recently where a fever case existed, and found the drain traps defective. I wrote the owner requesting him to provide stoneware gully traps properly connected to the drain. The owner employed a builder to do the work, but when the man had opened the ground he found the drain in a very bad condition, and I was requested to examine it. The owner's attention was directed to the defect, and he was requested to make the drain good. He, however, refused, and ordered the trench to be filled up. I reported the matter to my Council, and as the drain was in such a bad condition they passed a resolution that seven days' notice, under Sec. 41 of the Act of 1875, be served on the owner, and that if he failed to comply with the notice, I was, on behalf of the Council, to get the work done. On his non-compliance with the notice I engaged a builder to do the necessary work on behalf of the Local Authority. Now, as the Local Authority did not receive a written application, as stated in the section, will this prevent our recovering the expenses incurred in doing the work. Can you state any case bearing on the point?"

Answer.—The Local Authority should be enabled to recover the expenses incurred. The written application referred to does not exclude the Inspector from being a person who can give it, and as he has doubtless furnished a report in writing in his journal or otherwise, this would be sufficient. In the event, however, of the defendant's solicitor raising a technical objection to the written application, the provisions of Sec. 262 of the Act, which provides that "no rate, order, conviction, or thing made or done, or relating to the execution of this Act, shall be vacated, quashed, or set aside for want of form" should not be overlooked.

Late Chemist and Superintending Gas Examiner to the Metropolitan Board of Works and the London County Council.

(*Continued from page* 137.)

CHAPTER XVII.—MEASUREMENT OF CURRENT.

In order to measure a current of electricity, two instruments must be used, namely, the *ammeter* for measuring the quantity of electricity conveyed in the current, and the *voltmeter* for measuring the potential or pressure of the current.

These two instruments are connected up to the circuit in the manner shown in the diagram, Fig. 32.

There are many other instruments in use, such as *voltameters*, for measuring the actual quantity of electricity supplied to consumers, registering this like gas by a gasmeter; *wattmeters*, for measuring electrical power, and registering this like a voltameter, but—unlike the voltameter—taking both the volts and the ampères into consideration; *ohmmeters*, for measuring the resistance of conductors, &c. &c. But it is beyond the scope of these articles to enter into a description of these; consequently we will restrict ourselves to describing very briefly the voltmeter and the ammeter only, and the manner in which these two instruments are connected up to the circuit, as this is of importance in order to more fully elucidate the action of the electric current in a circuit.

The ammeter is connected directly in the circuit, so that the whole of the current used for the lamps or motors has to pass through it, and consists of a needle pivoted over a graduated scale in such a manner that the current passing through a *short thick* coil of wire of low resistance is utilised for deflecting the needle by the magnetic lines of force which it produces.

The voltmeter, on the other hand, is not connected directly in the circuit, but is connected to it at two points, one on the positive, and one on the negative wire, by a separate wire; and measures the difference of potential between those two points, usually close to the terminals of the dynamo. The voltmeter is often exactly similar in construction to the ammeter, with the difference that a very *long thin* coil of wire of high resistance—often many thousand ohms—is used instead of a short thick coil. In the case of Cardew's voltmeter, however, the deflection of the needle is brought about by the expansion of a long thin platinum wire caused by the heat produced as the current passes through it; but in all voltmeters the current has a very high resistance to overcome, so that only a very minute quantity passes through the instrument.

It is of inestimable value to electrical engineers that a circuit may be divided at any point, and joined together again by any number of conductors, and the current will not, as might be supposed, flow along the line of least resistance only, but it will flow along each conductor exactly in proportion to its conductance; that is, inversely in proportion to its resistance. If the resistances of two conductors be R and r, their conductances will be reciprocals of these values, or $\frac{1}{R}$ and $\frac{1}{r}$ respectively; their joint conductance will be the sum of their separate conductances, or $\frac{1}{R} + \frac{1}{r}$, and their joint resistance the reciprocal of this value, or $\frac{Rr}{R + r}$.

It is clear that the joint resistance of two or more conductors will be less than the resistance of either conductor singly, for the two conductors together present a greater area along which the current can flow than a single conductor, in the same way as there will be less resistance to the flow of water in a tin can with two holes in the bottom than in a can with only one hole, whose area is less than the joint area of the two holes; and provided the height of the water or the pressure of the water in the two cans is the same, the can with two holes in the bottom will conduct more water in a given time than the can with only one hole.

If R represents a resistance of 3 ohms, and r a resistance of 2 ohms, their conductances will be $\frac{1}{3}$ and $\frac{1}{2}$ mho respectively; their joint conductance will be $\frac{1}{3} + \frac{1}{2} = \frac{5}{6}$ mho, and their joint resistance $\frac{6}{5} = 1\frac{1}{5}$ ohms.—Note: The term *conductance* is used as the inverse of resistance, and *mho* as the inverse of ohm.

Let us now briefly examine the course of the current in the circuit represented in the diagram, Fig. 32, in order to arrive at some explanation of how one instrument measures the ampères of the current while the other measures the volts. At the commencement of this chapter we explained that the current flowing

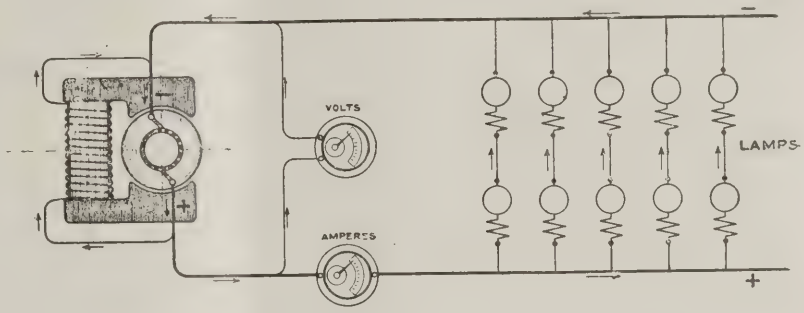

Fig. 32.

through a conductor measured in ampères is equal to the electromotive force of the current measured in volts divided by the resistance of the conductor measured in ohms; thus ampères $= \frac{\text{volts}}{\text{ohms}}$ or $C = \frac{E}{R}$.

Referring to our diagram, we will assume that the dynamo generates a current of 100 volts pressure, and that the voltmeter has a resistance of 5000 ohms. Assuming that all the lamps are switched off, the current which the dynamo will generate is dependent on the resistance of the voltmeter only; thus $C = \frac{100}{5000} = 0{\cdot}02$ ampères; but no current will flow through the ammeter, in consequence of the circuit between that instrument and the generator being broken; for the connection between the positive and negative wires is made only when the lamps are turned on, excepting between those points where the voltmeter is connected.

Let us now turn on the first pair of lamps, which have a joint resistance of 10 ohms. There are then two connections between the positive and negative wires, the voltmeter circuit having a conductance of $\frac{1}{5000}$ mho, and the lamp circuit a conductance of $\frac{1}{10}$ mho. Their joint conductance will be $\frac{1}{5000} + \frac{1}{10} = \frac{501}{5000}$ mho, their joint resistance $\frac{5000}{501} = 9{\cdot}98$ ohms, and the current which will flow through it with the pressure of 100 volts, $C = \frac{100}{9{\cdot}98} = 10{\cdot}02$ ampères. Of this current the

lamps will take $C = \frac{100}{10} = 10$ ampères, and the voltmeter the remainder, or $\frac{100}{5000} = 0{\cdot}02$ ampères; exactly the same as when the lamps were switched off.

In the same way, if the five pairs of lamps are turned on, there will be six connections between the positive and the negative wire, with a total conductance of $\frac{1}{5000} + \left(\frac{1}{10} \cdot 5\right) = \frac{2501}{5000}$ mho, and a joint resistance of $\frac{5000}{2501} = 1{\cdot}9992$ ohms. The current which will flow through the resistance at the same pressure of 100 volts, $C = \frac{100}{1{\cdot}9992} = 50{\cdot}02$ ampères, of which the lamps will take $\frac{100}{2} = 50$ ampères, and the voltmeter 0·02 ampères, as before.

Supposing we increase the pressure of the current to 200 volts, then, when the lamps are all disconnected, the whole current will pass through the voltmeter, and its magnitude will be $C = \frac{200}{5000} = 0{\cdot}04$ ampère; that is exactly twice as great as when the pressure was only half as great, or 100 volts. Further investigation will show that the current which flows through the voltmeter varies exactly as the electromotive force or pressure of the current, and is quite independent of the total current generated, or of any resistance which may be switched on outside the voltmeter circuit.

(*To be continued.*)

SOCIETY OF ENGINEERS.

NOTES ON CERTAIN DETAILS OF DRAINAGE CONSTRUCTION.

By Gerard J. G. Jensen, Member.

(*Continued from page* 201.)

The prevention of the foregoing evils lies, of course, in the arranging of the waste pipes upon the more modern and more satisfactory plan under which the waste pipes are constructed in a similar manner to soil-pipes (see Figs. 7 and 9), with the obvious difference in the diameters of the piping, and their mode of discharge. Main waste pipes from baths, lavatories, and sinks should, and need, in no case exceed 2in. or 2½in. in diameter, and should, unlike soil-pipes (under which term it is convenient to include the discharge pipes of urinals and slop hoppers), discharge over surface traps. Attention may, in passing, also be drawn to the fact that it is desirable to provide long waste pipes with slip joints, in order that expansion and contraction of the piping—due to the discharge of hot water—may take place without injury to the stack.

Reference has already been made to the 18in. long channel, which it is not unusual to provide between the discharge end of a waste pipe and the gully trap, into which the waste water is eventually conveyed. This channel is recommended in the model bye-laws of the Local Government Board, and certainly served a useful purpose, when it was the usual custom to leave fittings within the house untrapped. It then minimised the risk of entrance into the house of any drain air which, from some cause or other, might find its way through the water seal of the gully trap. Similarly, it reduced the quantity of foul air drawn into the house from decomposing deposits in the miniature cesspool, which then served the purpose of the modern syphon surface trap. At the present day the channel is, however, only, if at all, useful when waste pipes are constructed in the reprehensible manner described, that is, when the waste pipes are provided with open hopper-heads. In that case, should foul air pass the seal of the surface trap, only a proportion thereof will be drawn up the waste pipe, and liberated through the hoppers near windows. The remainder of the air will be excluded from the pipe by being discharged into the open air near the surface trap. Whether this is really advantageous is open to serious doubt. If there be any advantage, it is a

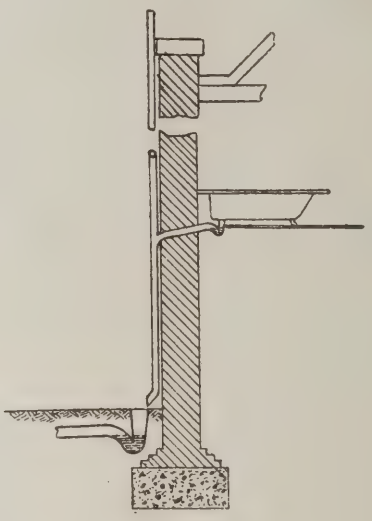

Fig. 9

question which is preferable, the remote risk of foul air passing the surface trap, and being drawn into the improperly-constructed waste pipe, or the almost certainty of a nuisance being created by decomposing deposits on the surfaces of the channel.

It may be urged that the channel should be periodically cleaned by hand. This certainly is done by the

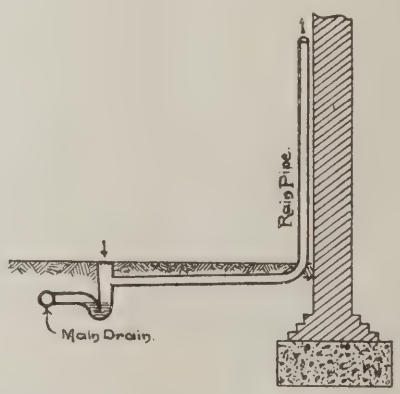

Fig. 10

few; but we have still to arrive at the time when the majority of householders will give even a thought to the condition of the drains, or bestow the care which the drainage system undoubtedly deserves. Happily the channel may be safely dispensed with under the system of waste-pipe construction advocated by the author, and if the waste pipe is properly connected to the surface trap, then not only will there be no danger from any foul air drawn into the waste pipe, but in addition, any foul air passing through the seal of the trap will be drawn into the pipe, and by it liberated at a safe point well away from all windows.

Whilst on the subject of waste pipes, the author desires to draw attention to a detail of construction

which he has now for some years adopted in his own practice, and which, although made public elsewhere by him, does not yet seem to be generally known or adopted. Under the present practice of secondary disconnection, by which a surface trap is provided at the foot of waste pipes and rain-water pipes, it frequently occurs that a comparatively long branch drain is left unventilated; the branch drain referred to being that connecting the surface trap with the main or other

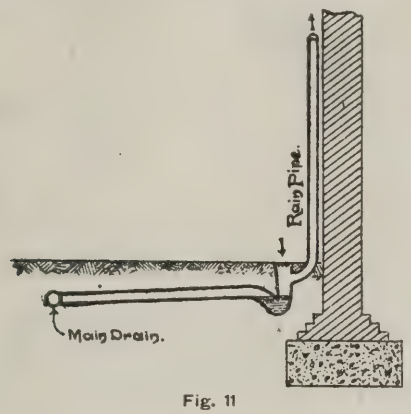

Fig. 11

branch drain, in which there is a current of air. If of appreciable length, such an unventilated branch drain is contrary to the principles of sanitation. On the other hand, the provision of a separate ventilation pipe for each such drain would be both costly and unsightly. A solution of the problem lies in placing the surface trap in proximity to the main drain, and continuing the waste or rain-water pipe to it underground. This will also avoid a 4in. branch drain which, in the majority of cases, is insufficiently flushed by the discharges of the waste pipe which it serves. The

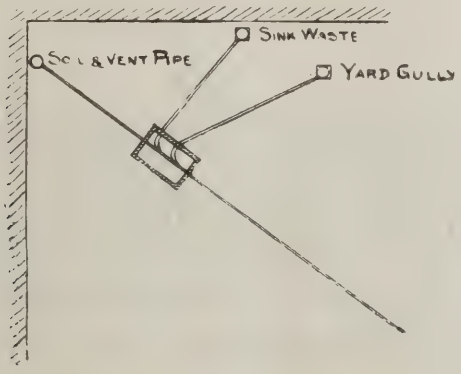

Fig. 12

method advocated is shown in Fig. 10, whilst Fig. 11 shows the alternative to be avoided. In continuing the waste pipe underground to the surface trap, it is, however, desirable to provide a cleansing eye—not shown in the illustration—at the change of direction in the waste pipe, in order that obstructions may be easily removed should they occur.

This plan of regulating the positions of surface traps with a view to the more perfect ventilation of the drainage system is equally applicable to manholes, the positions of which are not always chosen to the best advantage. Fig. 12, for example, shows the position, relative to drain inlets, which manholes frequently occupy. The arrangement, the author submits, could be greatly improved upon by constructing the manhole in the position shown in Fig. 13. By this means, in this instance, two unventilated and badly-flushed branch drains will be avoided. A slight saving in the quantity of drain piping used will also ensue.

In the construction of the manholes themselves, some improvement might frequently be made. Manholes are provided to give access to the drains, yet it is not unusual to find them so constructed that, for want of room, the drains discharging into them can only be reached by lowering a man down head foremost. This is a position in which, unfortunately, most men refuse to work. Again, a shallow chamber may have been built of sufficient size, but provided with such a small cover that a man wishing to plug the drain finds that,

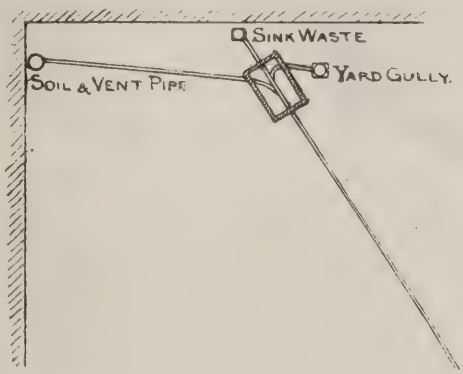

Fig. 13

by leaning into the chamber and balancing himself most uncomfortably on one hand, he can with the tips of the fingers of his other hand reach to just within an inch of the drain to be plugged. A third, and even more frequent mis-arrangement, is where the branch drains have been taken into the manhole near its outlet, leaving insufficient room for the insertion of drain rods, should that be necessary, for there is a limit to the pliability of these rods.

As regards the channels of open manholes—that is, of manholes in which there are no access pipes (Fig. 14)—these are perhaps best constructed of concrete properly rendered in cement. If, in addition, the whole of the interior surfaces of the manholes are similarly rendered, there is a greater possibility of

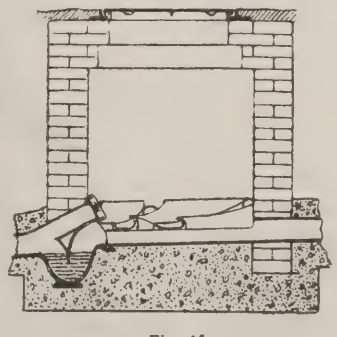

Fig. 14

obtaining a water-tight structure than if glazed channels and bricks are used. Unfortunately, however, the proper formation of the channels appears to be an utter impossibility with a great number of bricklayers, and if only such men are available, then certainly the best results are obtained by making use of suitably-shaped glazed channels. Attention must also be bestowed upon the channel benchings, since, if too flat, they will tend to collect deposits; while, if too steep, they will be difficult to stand upon.

Coming now to spigot-and-socket drain joints, it may be said that these are almost invariably made by insert-

ing some strands of gasket into the bottom of the sockets, and filling up the latter with cement or molten lead, as the case may be. The object of the gasket is, of course, to prevent the jointing material from entering the piping. Its employment, however, is, the author submits, not only unnecessary, but, what is more, most undesirable.

The gasket, being an organic substance, is found to decompose rapidly when moistened by sewage, and to sooner or later disappear altogether and leave a hollow space at each joint for the retention of sewage. This, of course, is opposed to the principles of sanitary drain-

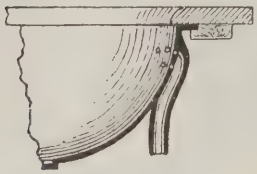

Fig. 15

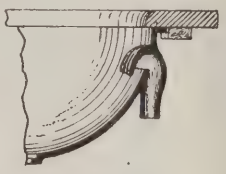

Fig. 16

age. Whilst the gasket lasts, moreover, it will also tend to harbour bacteria, which, in the case of pathogenic bacteria, is a serious matter, since the germs will multiply enormously in the meshes of the hemp. The joints may be well made without the use of gasket. In the case of cement joints, little more than care on the part of the workman is necessary to prevent an accumulation of cement in the piping, for, should it find its way into it, it can be easily removed before setting by the employment of a "badger." In the case of joints on iron piping, a few twists or ribbons of lead, or a cast lead ring, well caulked into the bottom of the socket, may be successfully substituted for the gasket.

The author lastly desires to draw attention to the overflows of the fittings of baths, lavatories, and sinks, some of which overflows render insanitary the fittings which are provided with them. The author refers to the overflows formed by holes in the sides of the fitting—

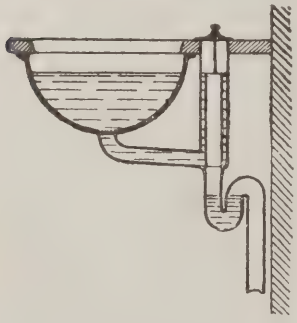

Fig. 17

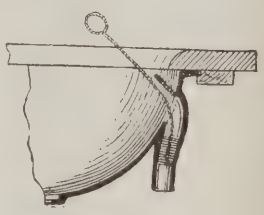

Fig. 18

see Fig. 15—to those in which the overflow pipe is masked by a shell or other ornamental device—see Fig. 16—and to others known as "secret" overflows and wastes, of which a type is shown in Fig. 17. These overflows, being but rarely flushed, and always inaccessible for cleansing by hand, soon become offensive, and it is to them that the mal-odours—"musty smells"—frequently experienced in bath-rooms, and similar apartments, are ascribable. Why these overflows should continue to be manufactured and used in new work is, perhaps, one of the wonders of house drainage, for their evils must be patent to all.

Better, and equally inexpensive, overflows are those in which provision is made for cleansing by the insertion of a brush, as indicated in Figs. 18 and 19, and those which consist of a short detachable pipe placed over the waste outlet (Fig. 20). The last-named, which are made in great variety of form, may be bodily removed from the basin for cleansing, and are easily replaced. The fact of their being in sight generally ensures their cleanliness. A similar overflow of recent introduction, which is illustrated in Fig. 21, is even self-cleansing, since, to empty the basin, bath, or sink, it is necessary to partly push the overflow pipe into the waste, thus ensuring a flush of water both to the interior and

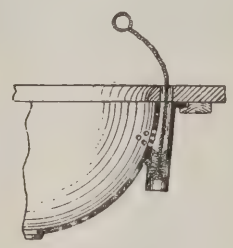

Fig. 19

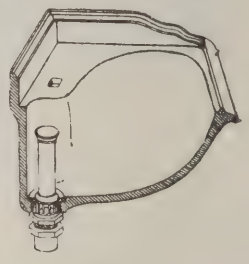

Fig. 20

exterior of the overflow pipe whenever the fitting is used. The author has of late frequently made use of fittings with these overflows, and has invariably found them to remain clean and efficient.

The author has now placed before the members particulars of what, in his opinion, are matters of considerable importance in the details of drainage construction, and has expressed his views thereon. He hopes his

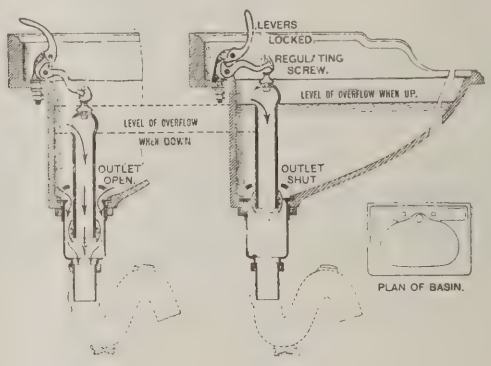

Fig. 21

paper will lead to a profitable discussion, in which the views and experiences of others will be given on these and any details not touched upon by him. He trusts that both the paper and the discussion may prove of practical use to those who, like himself, are engaged in that branch of the profession which deals with sanitation, and which, conscientiously and intelligently followed, is no whit behind any other branch in importance as regards the convenience and well-being of communities.

We shall give the discussion on this paper in our next issue.

THE Local Government Board has decided to issue a Provisional Order empowering the Drighlington Urban District Council to put in force the Land Clauses Act for the acquisition of land for sewage disposal works. The inquiry was held on January 30th before Mr. R. H. Bicknell, M.I.C.E. The District Council's proposal was strongly objected to by the owner, Sir R. Tempest. The scheme, as prepared by the engineer, Mr. John Waugh, C.E., of Bradford, provided for the whole of the drainage of the villages of Drighlington and Adwalton. The sewage on arrival at the Outfall Works is first treated in two large tanks by means of chemical precipitation, and then run on to four bacteria beds, the effluent from which is treated on five acres of land laid out on the intermittent downward filtration system. The total estimated cost of the scheme is £12,600.

TUBERCULOSIS—INFECTION, HEREDITY, PREVENTION, HYGIENIC TREATMENT.

By A. G. Young, M.D., Secretary State Board of Health, Maine, U.S.A.[1]

(*Continued from page* 176.)

At another of the congresses held in Paris for the study of tuberculosis, Dr. D'Hotel[27] gave the results of the study of outbreaks of tuberculosis in country villages in the northern part of France. The study was begun by his father and had been continued by the younger Dr. D'Hotel. The observations covered a period of more than half a-century. It is in the country that one can advantageously study tuberculosis with reference to the questions of infection and heredity, particularly in isolated country villages, where the inhabitants rarely change their habitations, and where there is but little communication with the outside world. Under these conditions the studies of the Drs. D'Hotel were carried out. The following are a very few of the series of cases of tuberculosis recorded by them :—

Observation 1.—The family X., father, mother, and three children, lived in a two-storey house. Previously no case of tuberculosis in the family nor in the house.

In 1884 a consumptive came to live on the second floor where he occupied two rooms, there dying at the end of six months. These rooms remained unoccupied. The owner's son stored wheat in them, and from time to time handled it.

In 1884 this young man, twenty-three years old, very strong, became tuberculous and died in seven months.

In 1886, thirteen months after, a younger sister, who had taken special care of him, and who had drunk and eaten with him, became consumptive and died in ten months.

In 1885, the eldest daughter of the proprietor, who was married and lived elsewhere, came to live in these apartments where the consumptive had died. She had four children, one boy and three girls; her husband was a strong man. During six months their health was exceedingly good, then the youngest child, a little boy of twelve months, strong and robust, who, until then had been healthy, but who spent one-half of his time on the contaminated chamber floor, now became sickly, and I observed an enlargement of the abdominal glands and diarrhœa. The child improved little by little, but the abdomen remained enlarged. The child had his teeth and walked, but remained delicate, and was subject from time to time to stridulous laryngitis. At times he coughed continuously and his mother said that for three months at a time he would be well and then he would have relapses.

When two years of age, I observed that the child had an enlargement of the left wrist, and at two and one-half years the left ankle became swollen. White swellings developed rapidly and suppuration occurred in three months. At the same time, the child became emaciated, coughed more and more, and died at three years, fifteen months after his uncle.

In 1886 a little sister, who sometimes lived in the apartments where the consumptive died, and sometimes in her sick uncle's room, had keratitis, which lasted for six months before any improvement. The next year keratitis appeared again, but was cured in two months. Since then her health has been good.

The other two children have remained well.

In 1890 the husband of the eldest daughter of the proprietor, with no hereditary history, had a continuous fever with pains in the joints, cough, oppression, on auscultation dispersed and transitory signs, diarrhœa, night sweats, hæmorrhages, emaciation. This condition lasted four or five months, then his appetite and health returned. This man, however, remained very pale.

Observation 3.—L. X., married a woman who became tuberculous and died in three or four years. One year later contracted a second marriage with D. X., in whose family there is no previous history of tuberculosis.

There was born to her one child, who lived. L. X. died of pulmonary tuberculosis at the end of four years He suffered about one year.

The second wife, D. X., had occasional febrile attacks in the year following her husband's death. In the second year of widowhood she married B. Z. Her health was rather poor, she had a husky voice without coughing much, and she took particularly good care of herself. Her husband had bronchitis and catarrh without any former history of these diseases in his family. He was an alcoholic. The son by her first husband lived to be twenty-five years old. He was brought up at home, but slept in the upper storey.

All the succeeding tenants occupied the same sleeping room, used the same bedding, and the furniture was not changed.

Observation 6.—Two tenements composed of two rooms under the roof. Two of the rooms were exceedingly low-studded; there were beds in all four rooms. By the doors being always open, these four rooms were really but one. The family was composed of the father, a strong man; the mother, a healthy woman, and nine children, all strong and well except two who died, one of diarrhœa at four months; the other, from the results of whooping-cough, all of which occurred a long time ago. Their maternal grandfather and grandmother died at sixty-four and sixty-five years of age, one of heart disease and the other of typhoid pneumonia. The paternal grandfather died at sixty-seven years, and the grandmother of typhoid.

No. 1.—It was in the midst of this family that a young commercial traveller died of consumption. He suffered from eighteen months to two years. He was the brother of the mother of these nine children.

No. 2.—During this young man's sickness a little boy two years old, who played continuously on the ground where the consumptive expectorated, was taken with tuberculous disease of the tibia and of the wrist which suppurated for six months, leaving cicatrices adherent to the bone, and destruction of a part of the second left metacarpal bone,

No. 3.—During the last five months of the uncle's sickness, a little girl was born. The invalid took particular care of this child. This child at three months began to have swellings on its wrists, shoulder, and thighs, which terminated in suppuration in three or four weeks each, white cicatrices remaining. At five months, abscesses recurred on the wrist, on the back of the hand, and on the scalp. These ulcers suppurated in about four months, leaving cicatrices adherent to the bone. There is partial loss of the fourth and fifth left metacarpal bones. This child had diarrhœa for two years, then was cured and now is six years old.

No. 4.—A girl, twenty-one years old, apparently in good health. One year after the uncle's arrival in the house, she was taken with enlargement of the submaxillary and cervical glands, with a cough and fistulas. She recovered and now her general health is good.

No. 5.—A son, twenty-three years old, well developed, hitherto perfectly strong, had hæmorrhages for three years. He has since died.

Observation 45.—X. and his wife, seventy-four and seventy years of age, had three children.

The first, a young seamstress sixteen or seventeen years of age, who had lived in the house mentioned in the fifth observation, died of consumption in twelve or fifteen months.

The second, a son twenty years old, died in five or six years, several years after the death of his sister.

[1] Reproduced, by special permission of the author, from the eleventh report of the Maine State Board of Health, U.S.A.

[27] "Congres pour l'Etude de la Tuberculose," 1893, page 64.

During this interval the second brother died of consumption also.

The father of these children, who had until then had robust health, suffered a great deal after his children's death. He had a number of attacks of hæmorrhage, and there were crackling rales at the apex of the right lung. His sickness lasted between ten and fifteen years, commencing from the death of his children. He has been well now for ten years. His father and mother died of old age.

This house consisted of a kitchen chamber with a dark closet attached, where each patient had slept in turn.

(*To be concluded.*)

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

BACTERIAL CONTACT BEDS AT SOUTH MOOR.

The ordinary monthly meeting of the members of this Society was held last Friday evening at the offices, 197, High Holborn, W.C. Dr. J. C. McVail, the president, occupied the chair, and those present included Drs. T. Eustace Hill, P. J. Allan, H. Kenwood, H. N. Richards, G. Millsom, T. Robinson, H. Beale Collins, E. F. Willoughby, F. E. Streeter, A. Newsholme, O. Field, E. H. Williams, A. N. Brind, Mr. W. Defries, &c.

The Council reported that they had arranged with the Royal Statistical Society for the meetings of the Society to be held at 9, Adelphi-terrace, W.C.

Dr. T. Eustace Hill, M.D., Medical Officer of Health to the County of Durham, read a paper on "Sewage Disposal Notes, with Special Reference to Bacterial Contact Filters." The subject of sewage disposal, he said, was one in which Medical Officers of Health must be interested, and for some time past he had been carefully observing the results obtained in certain sewage works. There had been and still is a difference of opinion respecting the best means of properly disposing of sewage, and it was a question affecting the public health interest. So far as he could ascertain, the problem had not been brought before the Society for some years past, and its discussion would not, therefore, be inopportune at the present moment. Although the question had long been interesting Medical Officers, it was only of late years that the proper conditions and agencies had been fully recognised. Dr. Hill then briefly traced the early history of sewage disposal by means of broad irrigation and downward intermittent filtration, chemical filtration, and precipitation. But in none of these processes was there any knowledge shown of the biology of sewage or the value of microbic action. Having referred to the Dibdin, Massachusetts, and Sutton experiments, he pointed out that it had been found that bacteria were capable of indefinite multiplication in sewage, and that bacteria existed in sewage capable of peptonising solid organic matter—a process comparable to that of digestion itself, and final nitrification. With the results of Mr. Dibdin's investigations into the periodical treatment of sewage on a comparatively large scale by passing it through filters of coke might be said to have commenced the revolution in the ideas of most chemists and sanitarians as to the disposal of sewage. It was then begun to be recognised that instead of destroying them, micro-organisms might be used as a chief factor in the purification of sewage. All disposal systems since brought forth have more or less depended upon microbic action for success. Dr. Hill then described later developments of the system, the Sutton beds, septic tanks, and so on, explaining the well-known principles upon which these experiments were based. He did not propose to enter into the relative merits of the various methods which could be mentioned, but to give the results obtained at South Moor, in the county of Durham, with bacterial contact tanks. Previously the sewage of the district had been treated on land and discharged into a river, the water of which lower down was used to partly supply another village with drinking water. The land available was quite inadequate for the proper purification of the sewage, and complaints were frequent. As a result of pressure, the District Council in 1898, on his recommendation, proceeded to construct on the land then being used for sewage disposal a set of bacterial contact tanks on somewhat similar lines to those at Sutton. The work was completed at the beginning of 1899, and occupied an area of about half an acre. The estimated population to be provided for in 1900 was 4560. The sewage was passed through a sort of detritus chamber, through a ½in. perpendicular screen into a collecting or subsiding tank, 35ft. by 29ft., and 5ft. in depth, and this held rather more than half the total daily flow of sewage. Thence it was discharged on to the coarse tanks, four in number, 45ft. square and 5ft. in depth; capacity, 85,000 gallons. The filtering material was a mixture of coke breeze and clinker, carefully screened, varying in size from 1in. to the proportions of a hen's egg; the four fine tanks were similar to the coarse tanks, except that the material was from ¼in. to 1in. There was no distribution of the sewage; it was allowed to run directly into the tanks. The tanks had been working continuously since February, 1899, without a stoppage. The raw sewage was first allowed to collect in the subsiding tank—it was a collecting tank rather than a subsiding tank—and after a few hours was run off into the coarse tanks. When the works were first started the liquid was only held up two or three hours, but in order to save attendance at the works during the night, the contents of the subsiding tank were run into the rough tank just before the attendant left the works, and remained there all night. No bad results followed the long contact, and it became the practice to allow the liquid to remain in dry weather in rough and fine tanks eight or ten hours; it was found a greater degree of purity was obtained than when it was only held up for two or three hours. The theory that the bacteria were drowned by long contact was thus found to be incorrect. Having explained in further detail the actual working of the tanks, which took all the storm water as well as the ordinary sewage, Dr. Hill explained that the detritus collected in the subsiding tank was very small, and was easily disposed of on a small plot of land twenty yards square without the slightest nuisance being caused. The effluent from the fine tanks was bright and sparkling and free from any trace of smell. Samples of the sewage and of the effluents were taken at all times with the result that it was proved that a satisfactory purification had taken place. On the average it was over 90 per cent. In the fine tanks, before bacterial action could have been said to have been properly established, the average of all samples analysed was:—Reduction of organic ammonia, 91·6; reduction by oxygen absorbed, 92·8. In May, 1899, the bacterial action had been fully established, and the results were still better according to the latest standards. The sewage had no manufacturing refuse, but the liquid was strong, urinous, and foul smelling. The population of the district was rapidly increasing, and with the present works the sewage from an additional population of 3000 could easily be dealt with. The total cost of land and tanks was £1450, or 7s. 3d. per head of the estimated population. This was paid for out of the current rates of the district, as the Local Government Board would not sanction a loan for the purpose unless there was provision made for passing the final tank effluent through land. The results of this work were sufficient to prove to the Local Government Board that land is unnecessary for bacterial sewage works, except in very special circumstances. The annual cost of maintenance did not exceed £30. The

points which had suggested themselves to him as a result of observations kept on the works were:—(1) That the passing of the sewage into a collecting tank before allowing it to run on to the coarse bed appears desirable, especially in small works, because distribution was more easily and quickly effected, less attention was required, but in no sense was that collecting tank a resolving tank; (2) the material employed did not appear to be of great moment, provided it was hard, not liable to break down into small particles or dust. In their case the breeze and clinker was obtained from local collieries for the cost of collection; the size for the rough tank appeared to be best at 1in. to the size of a small orange or less; for the fine tanks the material should be finer, although not too fine, as mistakes had in certain cases been made in this direction. Material which had passed a 1in. screen and been refused by a ¼in. screen was the most suitable material for fine tanks, and the results at South Moor made him doubtful whether any more suitable material than coke breeze could be obtained; (3) in neither coarse nor fine tank was there need for distribution over the surface; (4) contact tanks possessed advantages over some other systems where there is a constant flow of sewage through the tanks. Where there is a continuous flow distribution is improved. With regard to the reduction in capacity from the gradual depositing of mineral matter, Drs. Clowes and Dibdin had pointed out this reduction in capacity. At South Moor the same fact had been noted in regard to the coarse tanks. But there was no definite information as to the amount of reduction after two years' working; so far it was certainly not serious, and probably the tanks could continue working satisfactorily for several years without interference. Even in their case, if this reduction did seriously detract from the value of the contact beds, it would be an easy matter to put each one in turn out of order, and change the material in the tank; the greater part of the old material would be available, and the cost of screening would not be great. But this would never have to be done more than once in five years. There was no appreciable reduction of capacity in the fine tanks, nor was this likely to happen, for the effluent from the rough tanks contained practically no suspended matter. The period of contact of two or three hours laid down by Mr. Dibdin could be exceeded, and the sewage was held up eight, ten, twelve, or fourteen hours. With a strong sewage like that at South Moor probably the bacterial purification was more complete when the period of contact is from eight to ten hours than when held up only for two or three hours. At any rate, their percentage of purification was considerably higher than that at Sutton. A strong domestic sewage diluted to within six times its own bulk by storm water required one and a-half to two hours' contact in the tanks for sufficient purification to be obtained; therefore the capacity of the tanks must be such that a dry-weather flow can be, if desired, held up from eight to ten hours' contact. But the works at South Moor proved that ordinary sewage could be purified sufficiently in double-contact tanks. The change which the sewage underwent in the coarse tank appeared to be different to that which it underwent in the fine tank. The effluents from the coarse tanks were nearly black in appearance, and had a very characteristic smell, quite different from that of sewage; not only did it contain sulphuretted hydrogen, but there was a distinct earthy smell. He thought the change was largely an anaërobic change, similar to that in the septic tank, though undoubtedly in the upper portion of the bed the aërobic organisms would be at work. The effluents from the fine tanks were clear and bright, and contained large quantities of dissolved oxygen. With regard to automatic discharge apparatus, his experience with the various contrivances was not satisfactory. The chief objection to automatic apparatus was that it could not adapt itself to the changes in the flow of the sewage, and obviated that supervision which was so necessary in sewage disposal works. Among the objections to the double contact system one was the difference in level required being greater than in any other system. There must be a difference of 8ft. between the level of the sewage and the effluent, and if a collecting tank is used, as at South Moor, the difference is at least 12ft. In many districts that amount of fall is impossible. Another objection was that pathogenic organisms present in the sewage were also present in the effluent. Dr. Houston had shown that with regard to London sewage the B. coli communis and the B. enteritis sporogenes are nearly as numerous in effluents from coarse contact beds as in the sewage before treatment, and the effluents of double contact beds were also found to contain these organisms in large numbers, although to considerably less extent than the raw sewage. On the other hand, an efficient land treatment appeared to very considerably reduce the number of organisms. The danger of allowing an effluent containing pathogenic germs to flow into a river used for supplying drinking water was obvious. But further investigation into this matter was much needed, and in the meantime the Local Government Board were probably justified on insisting that the effluent from bacteria tanks and filters should pass through land or sand filters whenever the recognised watercourse was used as a drinking-water supply. He did not wish to be understood as advocating the bacterial contact system in preference to any other system which is capable of properly purifying sewage, but desired to give the results of his own experience, which showed that strong domestic sewage could be sufficiently purified in this way at moderate cost both for construction and maintenance.—Discussion followed, and a hearty vote of thanks was accorded to Dr. Hill for his paper.

NORTHAMPTON SEWAGE FARM.

A NUMBER of members of the Coventry City Council recently visited Northampton in order to inspect the Northampton Corporation sewage farm, which is regarded as amongst the best and most successful in England. Coventry has just established a sewage farm, and the object of the visit was to see the way in which the Northampton Town Council have laid out their farm, the manner in which it is conducted, the methods adopted for cropping, &c., and the results obtained. After the visitors had been conducted round the Town Hall and the Police-station, they were entertained to luncheon at the Grand Hotel, Northampton, by the Mayor. After a *recherché* repast, with his Worship in the chair, and Councillor Henry Green in the vice-chair, the loyal toast was honoured, and "Our Visitors" was proposed from the chair, and the visitors felicitously gave "The Mayor and Town Clerk." Subsequently carriages were ordered, and the company drove to the Houghton-road sewage works, which are soon to be removed. Leaving here, they proceeded to the Corporation sewage farm at Ecton. The whole of the arrangements at the farm were inspected, and interesting explanations were given by Councillor Green, Mr. Goosey, and Mr. Gubbins. The visitors expressed themselves as well pleased with all they saw, particularly with the effluent from the farm. When Northampton was again reached the company were entertained to tea at the Grand Hotel by Councillor Green, who was thanked for his hospitality. The guests expressed their gratification at their reception, and the courtesy they had received from every one they had met on their tour of inspection, and they congratulated the Town Council of Northampton upon the efficiency and condition of the sewage farm.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

The following paper was read by Mr. J. Allan, Member, at the fourth meeting of the present session, February 13th, 1901, when Mr. W. J. Wells, chairman of Council, presided:—

FIREPROOF CONSTRUCTION FROM A SANITARY POINT OF VIEW.

I do not think that any apology is needed for asking your attention to-night to the subject of fireproof construction, as practical sanitary science has now become so wide in its application as to include every detail of construction which is likely to have a beneficial effect upon the health of the community at large; although nine years ago, when the first examination in practical sanitation was held at the Carpenters' Hall, one of the candidates, when informed by the Chairman of Examiners that his paper did not show sufficient practical knowledge of construction to warrant them troubling him further, declared that he considered the examination more like one in building construction than sanitation.

In dealing with this subject, I wish to point out at the commencement that I use the word fireproof as it is ordinarily used and understood, and do not intend to raise the question as to what is and what is not fireproof, but to take the word as it is used and understood in the various bye-laws and regulations, viz., walls, floors, partitions, and roofs composed wholly or in part of incombustible materials; and I shall assume that all external walls are so constructed, and confine my remarks to floors, partitions, and roofs.

I think that fireproof construction has not received in the past, nor receives at present, from sanitary experts the attention it deserves. There can be no doubt that buildings, when the floors, partitions, and roofs are composed of incombustible materials, are much more sanitary than those with ordinary wood floors (with or without pugging), stud or quarter, or even brick-nogged partitions, and that buildings so constructed are and can be brought to a greater state of perfection from a hygienic standpoint.

No doubt the additional cost has in a great measure prevented the adoption of fireproof construction in ordinary dwelling-houses; such a thing is rarely met with except in the modern flats, where it is compulsory under the Building Acts, or in private residences, where cost is no object.

About eighteen months ago the writer was asked to get out an estimate showing the difference of cost between an ordinary wood floor for workmen's cottages, and a concrete floor finished with floor boards on the top and plastered ceiling below. The fireproof floor worked out at 45 per cent. to 50 per cent. higher cost than the ordinary wood floor composed of 3 by 9 joists, 1in. floor boards, and lath-and-plastered ceiling, over spans of 20ft. by 15ft.

The extra cost led to the abandonment of the idea, and ordinary wood floors were used. I believe that the difference in cost now would be from 55 per cent. to 60 per cent., owing to the increased price of steel joists.

One serious item in the cost of fireproof construction is the expense of the temporary centering, unless there are large quantities where it can be used several times over, and thus reduce the cost by spreading it over a large area. Still, I think that, notwithstanding the extra first cost, the question is worth our serious consideration, when we take into account the increased healthiness of the community as the result of more sanitary dwellings, the absence from danger of fire, and the less cost of repairs, all of which would follow from the adoption of fireproof constructed houses.

It is hardly necessary for me to give you a description of the general condition of the spaces between the joists, floor boards, and ceilings of an ordinary dwelling-house, after, say, ten or fifteen years' occupation, but, for the sake of contrast, let me occupy your attention on this point for a few minutes.

Those who have had occasion to cut openings in the floors of ordinarily built houses know what a mass of dust and dirt accumulates in the course of a few years in the spaces between the joists, floor boards, and ceilings, and which is, in the nature of things, a hotbed of disease germs, and a standing menace to the health of the occupants, and this dangerous mass is being continually added to every time the rooms are cleaned, by particles being forced through the joints of the floor; and in bedrooms where a case of infectious disease occurs, with the present system of wood floors, the danger from germs thus stored is greatly increased. No doubt the dangers I have alluded to can be, and are, guarded against to some extent by using tongued floor boards, but even then the accumulation of dust and germs will still be found to exist, and the spaces between the joists are the happy hunting-ground of rats, mice, beetles, and other domestic pests.

What I have said about the ordinary wood floors applies to a certain extent to the usual stud or quarter partitions. It is surprising the amount of dust and dirt that is to be found in the interior between the studs, which, like the space under the floors, becomes a hotbed of disease germs. These partitions are somewhat improved if the spaces are filled in with brick nogging, but even then they do not, in my opinion, form a desirable construction from a sanitary standpoint, as the plaster is liable to crack at each stud, and the cracks form receptacles for dirt and microbes.

With regard to roofs as usually constructed, they are liable to the same defects as already described, only that the dust mainly comes from the outside, and finds its way into the rooms through every chink and crevice, carried there by the air currents due to the difference in temperatures.

Having described briefly the sanitary defects of floors, partitions, and roofs, as ordinarily constructed, I will now endeavour to show how some of these may be obviated, or at least minimised.

In considering the use of concrete for floors and roofs, we are dealing with a very old form of construction, which was known to the Romans, and much used by them over nineteen centuries ago. Professor Middleton in his first book, "Ancient Rome," states that the whole of the upper floor of the "Atrium Vesta" was formed of a great slab of concrete 14in. thick, and about 20ft. span, being only supported by its edges, having no intermediate supports. In his second book, "The Remains of Ancient Rome," Professor Middleton mentions that the Romans used concrete for the construction of the Pantheon (which was erected about the beginning of the Christian Era), including the great dome, which is 142ft. diameter and 37ft. high, so that, although practically unknown in this country a century ago, it is really a return to an old system I am now advocating.

As to the many forms of patent fireproof floors time would fail me to describe them in detail, so that I will content myself by mentioning a few of the best known systems which are in use at the present time. Before doing so, I wish to call your attention to two sketches, which show, might I say, the maximum and minimum of strength and simplicity of construction. A diagram was shown of a section to a scale of one-twelfth full size of the floors, and mansard roofs of the new buildings recently erected at the Royal Observatory, Greenwich. The width between the walls is 22ft., which is spanned by 14 by 6 rolled steel joists of heavy section, placed from 3ft. 6in. to 6ft. 6in. apart to suit the piers of brickwork between the window openings, and arches are formed as shown,

the minimum depth at crown being 7in., and the maximum at haunches 13½in., with a rise of not less than 1in. per foot of span. The concrete is composed of hard coke breeze and Portland cement, gauged 5 to 1, the top or wearing surface of floor being finished with a hard trowelled granolithic face. Another sketch gave a section one-twelfth full size through the floors of the cloak-rooms, lavatories, and teachers' rooms of a public school, constructed to carry 2 cwt. per foot super, the span of floors being 20ft. 6in. by 13ft. 6in. in clear of walls, the space being divided the long way into three bays by 6in. by 5in. by 26 lb. per foot R.S. joists, on which were laid 3 by 1½ R.S. joists at 2ft. 3in. centres. The small joists were so placed in the thickness of the floor that there is 1in. thickness of concrete under them and 2in. on the top, the top 1½in. being composed of granolithic. The remainder of the concrete is composed of hard coke breeze and Portland cement, gauged 5 to 1, the 6 by 5 joists being incased in similar concrete, minimum thickness 1½in. The floors of caretaker's rooms are constructed in a similar manner, but the concrete is composed of coke breeze the full depth, on which are nailed wood fillets, to which the floor boards are nailed. The wood fillets, in my opinion, were unnecessary, as the floor boards could have been nailed direct to the coke breeze concrete, or better still, the concrete finished with a hard granolithic face, same as other rooms, which would have saved space, made a better job, and been cheaper.

The floors I have just described are such as can be made by the ordinary workmen employed by a builder.

I will now briefly describe some of the best known and most widely used patent systems of fireproof construction, which can only be carried out by the patentees or under their licence.

During the first half of the nineteenth century several attempts were made and numerous patents were taken out for fireproof floors, but not until Dr. Fox introduced what was afterwards known as Fox and Barret's floor was there anything that proved reliable or lasting. Since then we have Wilkinson's, Dennett's, and Dawnay's floors, all of which consist of rolled steel joists and Portland cement concrete in various forms. More recently we have Fawcett's, Homan's, Picking's, and Ward's floors, which are all of the lintol form of construction, being composed of fireclay, or gypsum tubes of different forms, which are notched at the ends, so as to rest upon and protect the lower flanges of steel joists, and are filled in to the required depth with Portland cement concrete, and finished on the top as required to take floor boards, mosaic, or granolithic.

Then there are Potter's arched floors, and the "Cunnah-Wright" system, where the steel joists are fixed further apart with corrugated sheets placed between, to carry the concrete in lieu of the fire-clay tubes. In the former the sheets are curved as well as corrugated, thus forming a series of arches, while the "Cunnah-Wright" sheets are flat, and have peculiar dovetail-shaped corrugations or grooves, which strengthen the sheets, and form a key for the plastered ceiling. Then we have Stuart's granolithic floors, Potter's flat floor, Banks' floor, the Expanded Metal Company's floor, Hayward's floor, and most recent of all, the Columbian Fireproofing Company's floor, with their special ribbed steel bars, which aim at using the minimum of steel with the maximum of strength, and succeed in a remarkable manner to do so. Especially is this accomplished in Stuart's floor, where the results are marvellous for the bulk of material used.

You will notice I have divided the floors mentioned into groups. Group 1: These floors are too heavy and costly to ever become generally used, and do not call for any special commendation. Group 2: These floors are more generally used, and are well known. Picking's floor, I think, is the best of the group, and is most suitable for general adoption in ordinary dwelling-houses because of its lightness, the small space it occupies, as well as being moderate in price. I think all this group would be improved if the tubes were made longer, so that fewer joists could be used, and thus the cost reduced. Messrs. Picking and Co. make a special arched form of tube for spans up to 3ft. 6in. between the joists, which deserves attention. Group 3 I think are still more suitable for general use, as they can be adapted to any class of building, and work out at moderate cost. Group 4 I consider the best of the floors now in use, and are likely to be more generally used in the future. Stuart's granolithic floor seems to me to be the best, from a hygienic standpoint, when the top of the floor is to be the wearing surface; but when small fillets or joists are used for the purpose of securing the floor boards, it again introduces the space between the floor boards and the top of the granolithic, which we want to get rid of.

Potter's flat floor, with corrugated steel rods, I think deserves attention for ordinary dwelling-houses. It takes up little space, is light, and can be finished with hard wearing face, or floor boards, nailed direct to the concrete. I have provided, as far as I could, some particulars and illustrations of the several systems of floors as published by the patentees, and must refer you to these for further details of the different floors.

I will now ask your attention for a short time to the construction of partitions. Fireproof partitions have not received anything like the amount of attention that floors have done, and there are not many systems in use.

When cost is no object, a 4½in. or 9in. brick wall can always be recommended, provided the plans of the various floors are arranged symmetrically, so that the walls come over each other to take the weight. There are several special bricks in use for partitions, which can be used in conjunction with fireproof floors, Picking's being specially worthy of notice. They are light, rigid, and take up little space, and can be had with glazed faces, plain faces for painting, or left with grooved surfaces for plastering.

The Cunnah-Wright system of partitions deserves attention as one of the best now in use. From particulars given it seems to be a sound and substantial form of construction, and is being largely used. This partition consists of their special corrugated sheets, fixed into a special section of H steel standards with channel cills and T heads, plastered both sides, finishing about 2½in. thick.

The Expanded Metal Company and Hayward Bros. both claim lightness and economy of space for their partitions, but I have a doubt as to their rigidness, unless stronger standards are used. They consist of light steel rods, secured top and bottom to the floor joists, tightened by screws, to which is fixed expanded metal lathing in the former, and Jilhmil lathing in the latter, but if any sag takes place in the floor overhead the tension of the rods would be destroyed, and the stability of the partitions endangered.

Potter's partitions are composed of light concrete, with corrugated steel rods embedded in same; but they require temporary boarding, as the concrete is filled in *in situ* in a soft state. They are very suitable for partitions which do not go the full height from floor to ceiling, such as are used for cubicles, &c.

With reference to roofs, the various systems of construction used for floors can be, with little variation, applied to roofs—which can be flat and asphalted, or mansard with the sides slated or tiled, the slates or tiles fixed direct to the coke breeze concrete, and the flat portion asphalted, or otherwise made weather-proof.

In conclusion, the ideal dwelling-house, from a sanipoint of view, ought to have fireproof floors, finished with hard cement surfaces, without floor boards; the

kitchen and other offices left bare; bedrooms to have a few loose mats or rugs where necessary. The floors of the other rooms could be covered with some of the various kinds of cork carpet, or lino, or ordinary carpets could be fixed by using lead or oak plugs, as necessary. (I have seen this done in theatres, where all floors were finished with cement surfaces.) Solid fireproof partitions, with all angles at junctions of walls and floors rounded, and finished with hard plastered surfaces, including the main walls, and painted and decorated in oils, in preference to wall paper or distemper colours. The upper floor, if the roof is not fireproof, ought to have a concrete fireproof ceiling, which would vastly increase the comfort of the rooms, rendering them cooler in summer and warmer in winter.

It may be said that what I have described is only an ideal, and not practical; to which I reply that what I have just described is being carried out to a certain extent in all modern hospitals, asylums, and workhouses, and surely it would be truer political economy, to provide properly-constructed sanitary houses for the community at large, to keep them in health, and prevent disease, than to provide *such only* for those who are suffering from disease, sickness, or old age, when by doing so health and strength would be preserved, and the arrival of infirmity from disease and old age delayed; and further, such methods of construction are being carried out in America, as the following extract, from a very courteous letter I received on this subject from the manager of the Columbian Fireproofing Company, Limited, will show:—"One building in Indianopolis ('The Majestic'), one of the finest in the West, has no wood floors, and the offices are very comfortable to sit in. This building was built particularly from a sanitary standpoint, as it is owned by a doctor, who objected to wood floors on the ground of dirty water, &c., getting into the joints."

In bringing these notes to a close, I wish to acknowledge my indebtedness to the following for their courtesy in giving me information, and placing at my disposal the various samples and photographs which you see here to-night:—Stuart's Granolithic Company; Mr. Thomas Potter, of Potter and Co.; Mr. G. C. Picking; the Fireproof Partition Syndicate, Limited (Cunnah-Wright Patents); Hayward Brothers and Eckstein, and the Expanded Metal Company.

DISCUSSION.

The CHAIRMAN, in rising to propose a vote of thanks, said:—

The subject of the paper which Mr. Allan has so ably placed before us this evening is one which must appeal very forcibly to those who are desirous of adopting the best form of construction for floors and partitions to dwelling-houses, both from the standpoint of sanitation and fire resistance. There can be no difference of opinion as to the desirability of abolishing the old system of flooring and quarter partitions, forming so many receptacles in their vacant spaces for objectionable matter of every description. The difficult problem appears to be to find some mode of construction by which the well-known evils of the old system can be avoided, and, at the same time, to obtain those results at a cost which will admit of a fair interest on the outlay. Many of the examples we have before us without doubt are excellent, and for flats and other large buildings a sufficient rent could be obtained to justify the necessary expense, but in the case of moderate-sized dwelling-houses and of dwellings for the working classes the extra cost of 50 per cent. would appear to be a serious item, and the necessarily increased rent required to obtain interest on the capital would be considerable. Looking at the question from a health point of view, it would doubtless be to the interest of the occupants to pay the increased rent, and in all probability it would be economical in the long run, but I fear the average workman would not see the matter in that light. One objection in some of the fire-resisting floors is the space left between the surface of the concrete and the under side of the floor boards, and I think it is far better to fix the flooring direct to the concrete with no intervening space, placing a thin coating of damp-proof composition between boards and concrete. With these few remarks, I beg to propose a vote of thanks to Mr. Allan for the care he has taken in preparing the matter for our discussion.

In seconding the vote of thanks proposed by the Chairman, Mr. F. J. RAYNER said he must personally thank Mr. Allan for his very able paper, as it was one he had looked forward to, being a matter he had taken a special interest in for some time. Mr. Rayner agreed with the reader that the subject is one that should be more thoroughly dealt with by sanitarians, for fire-resisting floors and walls were highly conducive to cleanliness, and prevented to a vast extent the gathering and multiplication of disease germs, as compared with wood floors and papered walls.

Mr. H. M. DOVE had much pleasure in supporting the vote of thanks. He would like to mention that flooring composed of coke breeze concrete was not considered by many district surveyors as being of fireproof construction, and that where it was requisite that fireproof flooring or staircases had to be constructed, they required the sanction of the London County Council before they would allow the use of coke breeze in the concrete, as it was not proof against fire, it allowing heat to be freely transmitted and conveyed to surrounding material. As to the space mentioned as usually existing between the upper surface of a concrete flooring and the joists and wood flooring above, he now usually got over that difficulty by using dovetailed-shaped joists, covered with tar, &c., and embedded them in the concrete, so as to be of the same finished surface, upon which he spread a coating of pitch and tar, or asphalt, and laid the flooring directly upon same, thus doing away with the open space, and obtaining the advantage of a wood block floor at a much lower cost. He would also mention that concrete formed as an arch was not of the nature of an arch, but only as a slab of unequal thickness, and that if a slab of the average thickness of the arch were laid in one thickness, greater strength would be obtained, and at a slightly less cost, owing to a level surface having to be found in the place of the usual arched centerings. It was impossible to form an arch of ballast and cement in a dry state, as could be done with bricks, stone, or blocks. Therefore the whole of the strength was in the material used to bind the ballast into one mass, the strength being that of tension and cohesion, and not compression.

After several other members had spoken, the vote of thanks was put and very heartily carried.

In acknowledging the vote of thanks, and replying to the remarks made, Mr. ALLAN said he quite endorsed what Mr. Wells had said about the cost being the great barrier, which hindered the introduction of fireproof construction in ordinary dwelling-houses, and regretted that at the present time, when so much was being done to solve the problem of housing the masses, that the extraordinary increase in the cost of labour during the past ten or twelve years made the solution so much more difficult. Not that he grudged the payment of fair wages, but he deplored the ever-increasing difficulty of obtaining anything like a fair return of work for the wages paid. In his opinion the London County Council were mainly to blame for the present state of matters, owing to their having practically backed the trade unions by insisting upon a uniform rate of wages being paid without any regard to the amount of work done in return. The fact that it had become a general practice for all public bodies following in the wake of the London County Council to insist upon a certain rate of wages

being paid, without any regard to the amount of work done, was nothing less than robbing one-half of the ratepayers for the benefit of the other. He considered that there ought to be a standard fixed for the amount of work to be done as well as the rate of wages to be paid. If this were done he was sure it would go a long way in solving the housing question. Everyone who had to do with the carrying out of work knew that while the rate of wages in the building trade in London had been increased about 12½ per cent. during the past ten or twelve years, the actual cost of labour had increased 30 to 40 per cent. In reply to a question by Mr. Dove as to why the floor, shown by Fig. 1, was arched, as he considered it would have been just as strong if made flat, the thickness of the thinnest part, Mr. Allan said that he was not responsible for the section shown, but he differed from Mr. Dove, and considered that the arched form of floor was the strongest and best for the bulk of materials used; in proof of which he read an extract from a report by Mr. Baldwin Latham, on the fall of some concrete floors at Cambridge, where he says that "concrete floors between iron girders should be cambered or curved, so that the strains may be in compression and not in tension."

WEDNESBURY SEWAGE FARM.

We are indebted to Mr. T. Wicks, A.S.I., engineer and superintendent of the borough of Wednesbury sewage farm, for the following details of its working:—The dry-weather flow of sewage is from 500,000 to 600,000 gallons per twenty-four hours, and the maximum flow of storm water from 3¾ to 4 million gallons. Two-thirds of the sewage flows to the works by gravitation, the remaining third is raised by four of Shone's pneumatic ejectors, which are located at the "low levels" of the town, and are operated by compressed air conveyed in pipes from the works. The sewage is brought down to the works by a cast iron main outfall sewer 2ft. in diameter, and is discharged into a screening chamber where two screens of ½in. and ¼in. mesh are located. Here the coarser matters are arrested previous to chemical treatment. Immediately behind the finer screen is a valley 8ft. by 5ft. by 3ft. over which the sewage flows, and into which road detritus and the heavier mineral matters subside. The sewage now flows through a 3ft. by 2ft. blue-brick culvert or carrier for a distance of twenty yards. Here is fixed a Keirby patent mixer for supplying precipitants to the sewage. At the present time this mixer is not working, so that the sewage flows on along the main carrier for another eighty yards, when it enters the sewage ducts from which it can be diverted into any or the whole of the tanks. At the entrance of the duct the alumino-ferric is added, the proportion being regulated by the nature and volume of the sewage, and by the time the sewage enters the tanks the chemical precipitant is thoroughly incorporated with the sewage. All the tanks are arranged on the continuous-flow principle, the sewage entering at the bottom and the effluent falls over a weir at the opposite end.

The precipitated sludge is drawn from the bottom of the tanks by gravitation to a sludge-well, from which it is raised by the Tangye centrifugal pump into the open tank. After standing for a short time the supernatant fluid is run off the surface of the sludge and the latter runs into the rams. From these it is forced by compressed air into the sludge presses. Two per cent. of lime is added during the pumping to assist in the process of pressing. The effluent after leaving the tanks flows along the ducts to five clarifiers, and here all flocculent and fatty matters are arrested so that the clogging of the surface of the filters with an objectionable deposit is obviated. The clarified sewage now flows to the four polarite filters, and here two troughs are provided, one on either side for the equal distribution of the sewage. The filtrate can be passed either on to the land or directly to the river. The night flow, after precipitation, is disposed of on the land filter beds.

Experiments upon the biological purification of sewage have been conducted during the past two years and are still progressing. During these investigations several methods have been introduced, including open septic tanks, contact beds of coarse material, covered septic tanks (not air-tight), and filters constructed of coal, granite, polarite, coke breeze, furnace clinker, and broken potsherds. These experiments are being watched with considerable interest, and it is believed that the results will be satisfactory.

National Health Society.

OFFICIAL TRANSACTIONS.

Lectures in Wales.—One of the Society's lady lecturers has lately been engaged in a short tour in North Wales under the directions of the Girls' Friendly Society. The following places were visited:—Bangor, Llanfairfechan, Penmaenmawr, Llanfair, Llandegai, Menai Bridge, and Holyhead. The lectures throughout were well attended, and much interest was evinced in the subjects dealt with, the associates and other ladies attending the course, as well as the members of the Girls' Friendly Society, expressing their appreciation of the lecturer's teaching.

Oxfordshire.—The teaching on first aid, nursing, &c., is very much appreciated in this county, Miss Christine Hall reporting that at some of the centres she has crowded audiences. Miss Hall is preparing candidates for the Society's examinations, and it is hoped that a large number will present themselves at Oxford when the examination is held.

Examinations.—A week's examination tour is now being held in Lincolnshire by one of the Society's examiners. Miss Morgan, having finished her work in this county for the session, is now undertaking a course of lecturing in Suffolk.

Lectures at Berners-street.—The subject of Dr. Squire's lecture on Tuesday next, March 19th, will be "The Muscular System." Dr. Squire's lectures are given on Tuesdays at 2 p.m. and Fridays at 4 p.m.

Dr. Kenwood's lectures on "Public Health and the Duties of Sanitary Inspectors" are held on Mondays at 4 p.m., and Thursdays at 3.30 p.m.

Mr. E. A. S. Fawcett held an inquiry at Kingswood on Wednesday in last week on behalf of the Local Government Board respecting the proposal of the Urban Council to borrow £27,000 for the purpose of carrying out a sewerage scheme. There was a numerous attendance, including several gentlemen who opposed the proposed site for one of the outfall works comprised in the scheme. The Clerk to the Kingswood Council, replying to the Inspector, said that they had no efficient arrangement for the disposal of the sewage in the district, and certainly they were running some risk to the health of the district through having no proper sewerage system. Their present system was by cesspools. There were two principal brooks into which the sewerage of the district ran, viz., Cheltenham Brook and the brook at Lantern Bottom, and both ran into the Siston Brook, and from thence into the river Avon.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

MARCH 14, 1901.

THE HOUSING QUESTION IN THE LORDS.

THE Marquis of Salisbury was tackled in the House of Lords last Friday respecting the intentions of the Government with regard to the housing of the working classes, and the introduction of the subject led to an interesting debate. It cannot be said, however, to have been very fruitful. The subject arose through the complaint of the Earl of Portsmouth and the Marquis of Northampton—that Lord Salisbury in his speech last December at the conference of Conservative Associations had counselled the Conservative party to increase their hold on the metropolis by making this great question, in which Londoners are so deeply interested, specially their own. It was urged that it was unworthy of the Premier to endeavour to make a party question out of what should be regarded as a national question, without distinction of party. Lord Salisbury's counsel to his followers practically amounted to this—that here was a great social evil, a matter of national concern, growing more serious every day, and that if they were to take it up earnestly, and deal with it successfully, they would reap the gratitude of the electors. Any legislation on the subject must come from either a Conservative or a Liberal Government, and as a Conservative Government is in power, and is likely to remain in power for a good many years, it is fitting that they should consider what policy it is possible to propound. It would certainly be deplorable if the question were made a party question to the extent of dividing political parties upon it, or if the one party should conceive it to be its duty to oppose whatever the other party might propose. But of this we trust there is little fear. We shall welcome a measure of reform from whatever source it may proceed, and provided it is in itself acceptable, we need not concern ourselves with the motives of its authors. It will be sufficient that the public weal is served. Lord Salisbury's speech in December, however, undoubtedly raised certain expectations that the Government were contemplating action of some sort, and he was invited to make a statement of the Government policy. On this subject he had little information to give. He dwelt at length on the immense difficulties with which the whole question is surrounded.

Foremost among these he placed the financial difficulty. No substantial assistance, he opined, could be expected from the London County Council, and as for the Imperial Treasury he held out little hope in that direction. "At present," he went on to say, "we rely to a certain extent on the Local Authorities, who have behaved so well, but we are relying largely, as we have always done, upon private enterprise. That has been our reliance from the first, and when you can find some adequate substitute for it I think that private enterprise must be to the end our main reliance." He admitted that the Government were deeply sensible of the great importance of the question, and deeply anxious to do whatever could be done to remedy the evil, but time and information were essential. He intimated in plain terms that the time of Parliament was already so fully mortgaged for the present session that nothing could be expected this year. For the future he would hold out no promises; but he did throw out a hint that next year the President of the Local Government Board might be in a position to announce some proposals to alleviate matters.

Beyond this, as far as a positive policy is concerned, the Prime Minister was guardedly vague and ambiguous. With these assurances, such as they are, we must for the time remain content.

That the statement contains nothing in the nature of a pledge is a cause for regret, but it is the nearest approach to one we are likely to get. Whatever may be the intention of the Government in dealing with this question, it is quite evident that public opinion in the country will not rest content much longer with the policy of shilly-shally, and unless the Government realise this fact, we are afraid the Premier's sanguine hope of remaining in power for a good many years will be rudely shattered.

The Small-pox Epidemic.

Observations of the progress of deaths from small-pox in London during the thirty years from 1845 to 1874 have established that the seasonal activity of small-pox is greatest in the first six months of the year. April and May are the months most favourable to its spread, but with June comes a turn, and the decline continues during the latter half of the year. The history of the epidemic in Scotland at present gives indications of bearing out this experience. After a period of decline there has come a revival, the renewed activity in Glasgow being very marked. The weekly return of the Medical Officer of Health for the week ending last Friday showed a total of 446 cases under treatment in hospital at the close of the week, as against 385 for the preceding Friday. The issue of the daily bulletins, which had been discontinued for a time owing to the decrease of the epidemic, had been resumed by the Sanitary Department, and further and more vigorous measures have been adopted to endeavour to check and stamp out the disease. The staff of thirty special inspectors, who have been engaged in a house to-house visitation of the infected districts, has been supplemented by twenty additional Inspectors, who are trained vaccinators, and whose chief duty is to go from house to house offering free vaccination to all inmates. When the daily roll of cases began to diminish a few weeks ago, there was at once a falling off in the rush for vaccination, and it is largely to this fact that the subsequent serious recrudescence of the epidemic is attributed. The falling off in the demand for re-vaccination, at a time when an increased seasonal activity of the disease may be looked for, is viewed with concern by the Authorities. Their difficulties have not been lessened by the holding of a meeting of anti-vaccinationists, honoured by a special visit from Councillor Biggs, of Leicester, for the purpose of instructing the citizens of Glasgow in the example of Leicester, and discrediting vaccination as a preventative. Mr. Biggs' mission at so critical a period is certainly an extraordinary one, and though he professes his object to be to strengthen the hands of the Corporation, the answer of the Lord Provost, that he cannot be regarded other than as a hindrance to the work, will meet with hearty approbation. Even had the Corporation no other guide than their experience during the course of the present epidemic, their attitude could not have been otherwise. For a feature of the epidemic is the number of victims over thirty years of age who have not been vaccinated since childhood. Among the patients now being admitted to hospital there is not one who has been recently vaccinated. The neglect of re-vaccination is not, we are sure, due to any disbelief in its efficiency, but rather to a feeling that the danger is passing. That idea must be dispelled. It is satisfactory to know that in Edinburgh, where there are as yet but few cases, the demand for re-vaccination, in consequence of the fear of an invasion of small-pox from Glasgow, has been so great as to tax to the utmost the resources of the Health Department. Sir Henry Littlejohn and his staff have been kept very busy. The daily arrival of a thousand tubes of glycerinated lymph is practically exhausted before noon every day. The poorer classes are taking full advantage of this precautionary measure, and the Authorities are determined, if possible, to keep the enemy outside their gates.

The Arsenic Poisoning Inquiry.

In his evidence before the Royal Commission on Arsenic Poisoning, Dr. Nevin, Medical Officer of Health for Manchester, made a number of practical suggestions as safeguards against the introduction of arsenic into foods or drink. They were as follows :—(1) That manufacturers of food and drinks in the preparation of which chemicals are employed should be required by law to have printed in clear characters on any orders sent to the vendor of such chemicals the words, "To be used in the manufacture of food or drinks," as the case might be. The words foods or drinks to include materials intended for immediate consumption, as well as materials (such as brewers' sugars) to be used in the preparation of foods or drinks. (2) That persons supplying chemicals to be used in the manufacture of foods or drinks should be required by law to affix conspicuously and securely to each consignment of chemicals to be used for such purpose a clear printed statement, in adeqate size of type that the materials supplied are "for the manufacture of foods or drinks." Such a statement should also be required to be printed on invoices of such consignments. (3) That without such statement conspicuously affixed to any consignment of chemicals it should be illegal under a penalty to use chemicals for such consignment for the manufacture of foods or drinks. (4) That as regards malt and hops and other materials used in brewing, it should be illegal for such materials to be contaminated with arsenic. (5) That the Foods and Drugs Acts should be amended so as to ensure that, in case of any deleterious contamination occurring in beer or stout, it may be possible to trace the source of the contamination, and so to ensure the destruction of the deleterious article.

The Peril in South Africa.

From various sources we learn that sanitary affairs are at a very low ebb in South Africa, even in those places untouched by the operations of the war. The Medical Officer of one of the suburbs of Capetown reports an outbreak of typhoid, and "regrets to have to conclude

from the evidence of statistics that the public health of the municipality has deteriorated during the year, owing to a gradually increasing effect of deficient sanitation." Out-of-date systems of night-soil disposal are fruitful in the creation of nuisances. These are set forth by a dweller in Woodstock, who says that "one cause of complaint, and a good and sufficient cause, is the removal of the pails at such an early hour in the evening that to walk in the streets after 9.30 of an evening is to fill one's system with nauseous shudders and to cause the passer-by to wonder if the time is the twentieth century—the age of hygienic and sanitary science—or one hundred years ago. Night after night the filthy vehicles rumble through the streets at the hour when most of the populace are enjoying the none too many beautiful evenings following on a day of toil. The approach of the vans with their fœtid cargoes is the signal for a rush indoors, and tightly-closed doors and windows must remain perforce closed till it is time to retire—the calm, cool wind of heaven poisoned at this early hour." The state of the streets is also a matter of consideration. At certain places are yards, in most cases occupied by tenements crowded with coloured folk, whose ideas of a hygienic life are certainly somewhat elementary. Trickling down from these hidden plague spots comes a filthy stream of thick liquid—it has long ago ceased to be water—gathering in the pools and crevices in the badly-formed gutterings, it lays exposed to the hot rays of a summer sun until the merciful rain perchance falls and washes it down, or the Cape "doctor" covers the festering sores with sand or dust. Time after time does the street scavenger, in cleaning out the storm-water traps, lay the mass of evil-smelling sludge gathered from the base of the trap upon the open roadway, till it dries and is kicked about, only to be gathered again in the course of evolution. If these conditions are not soon altered South Africa will be little better than an open cesspool.

The Dublin Death-rate.

A DEATH-RATE of 49·9 per 1000 is a very serious matter, and happily not often experienced in this country. But such were the figures Sir Charles Cameron had to put before the Dublin Health Committee at its meeting last week. The true meaning of these figures may be realised when compared with London, or the thirty-three great towns of Great Britain. In the former it was 20·9, and the latter 21·5 per 1000. Commenting on this serious position of the Irish metropolis, the *Freeman's Journal* tells us that the character of the districts where the death-rate is highest is particularly instructive. They are the districts where the poor are crowded together in unsanitary habitations. Every investigation that has been made reveals the fact that the unsanitary housing of the poor is the festering evil of the social life of Dublin, fruitful of immorality, disease, and death; yet no strenuous, active, persistent effort seems to be made to tackle that evil and conquer it. Now and again we have a few artisans' dwelling-houses built by the Corporation or by a private company. But the portion of the poor they can accommodate is so small that they are not missed from the vast swarm of suffering and perishing humanity in the more fœtid and unsanitary districts of the city. The public demand impatiently what has been done, and what it is proposed to do, to check this great and growing evil. Constant and efficient inspection was recommended. Have we such inspection? Strenuous, unfaltering rigour on the part of the Corporation in enforcing the sanitary regulations is demanded. Is that rigour universally and impartially displayed? This is not a question for doubt or delay. "While the Corporation wait and argue," continues our contemporary, "the people are dying like flies. The poor are the first sufferers, perhaps the chief sufferers. But they are not the sole sufferers. Disease is no respecter of persons or classes. Issuing from its habitual lurking-place in some squalid slum, it invades the rich and fashionable quarters of the city, where it strikes down its victims, man or woman, young or old, from the old man tottering on the verge of life to the infant just entering on it, with the same inexorable certainty. The rich are scourged for the neglect of the poor by the deaths of many in whom their heart's affections are centred."

No More Cold Rooms.

WE have to travel across the Atlantic to realise what can be really done in the way of communal co-operation, for what appears to be impossible in old countries becomes eminently practical in the new cities of the Western hemisphere. We are only just awakening to the utility of electric traction; but our brethren in America, when they plan a town, the very first thing provided is the electrical railway, and it is made ready for the people before they arrive. But enterprise is going a step further in the city of Churbusco, Indiana. A plan has been devised for heating the buildings with hot water, which is to be supplied just in the same manner as the ordinary domestic supply. Large mains have been laid 3ft. or 4ft. below the ground, and these are protected by many layers of corrugated paper and wood. Specially-constructed boilers have been provided at the central station, and from these hot water is sent forth to all parts of the city. When the housewife desires her rooms to be heated, all she has to do is to turn on the tap, when the water flows through the pipes and radiators in a continuous stream, and in a very short time brings the atmosphere of the room up to the desired temperature. It is said that the system of regulation is so good that the heat can be controlled simply by reducing or increasing the flow of water as the occasion may require. Eventually the water finds its way back to the central station, where it is re-heated. Exhaust steam from ten engines is utilised for heating, and the water is circulated through the streets and buildings by means of a centrifugal pump The experiment is creating considerable interest in the neighbouring towns and villages. If it proves successful, an immense amount of labour will be saved, more

particularly in business houses, and much will be done to keep the city clean and free from smoke, as well as the interior of the houses—two eminently desirable things in all places.

Food Inspection in the City of London.

The Board of Agriculture does not appear to be quite satisfied with the present method of food inspection in the City of London. In a communication just addressed to the Health Department of the Corporation, it is pointed out that last year only 168 samples were analysed, and that the average for the last five years has been under 150 per year. This might be sufficient if the census population represented the condition of the City during the daytime; but when we remember that more than half a million people find their employment within its borders, and that these obtain their food from the stores and shops of the locality in which they are engaged, it will be seen that it is totally inadequate. The Board of Agriculture very properly suggests that a responsible Inspector should be appointed; that from 500 to 600 samples should be taken annually; and that the officer should be encouraged to add to that number in order to test fully the purity of the food and drugs sold within the City. The suggestion is opportune just now, for the City is about to appoint a new analyst. The additional Inspector might be decided upon at once, and both officers enter upon their duties together. We would also recommend that attention should be paid to some of the eating-houses and coffee-shops, which keep springing up in every part of the City. The concoctions dispensed at these places defy the descriptive powers of ordinary individuals, and not a few would be glad to know the result of an analyst's inquiry into their composition. We confess we are among the number.

FORTHCOMING MEETINGS.

March.

Friday 15th.—Sanitary Inspectors' Association. Dinner at Holborn Restaurant. Postponed from February 15th.

Friday 15th.—Sanitary Institute—Lecture to Sanitary Officers at 7 p.m. "Sanitary Appliances," by W. C. Tyndale, M. Inst. C.E.

Saturday 16th.—Inspection and Demonstration at the Sewage and Destructor Works, Ealing, at 2.15 p.m., conducted by Charles Jones, M. Inst. C.E., Engineer and Surveyor to the District Council.

Saturday 16th.—Lecture to School Teachers, Bedford College.

Monday 18th.—The Sanitary Institute—Lecture to Sanitary Officers at 7 p.m. House Drainage, by W. C. Tyndale, M. Inst. C.E.

Tuesday 19th.—The Sanitary Institute—Lecture to Sanitary Officers at 7 p.m. Water Supply, Sources of Supply and Distribution, by Prof. Henry Robinson, M. Inst. C.E.

Tuesday 19th.—Royal Statistical Society: Prize Essay on "The Results of State, Municipal, and Organised Private Action on the Housing of the Working Classes in London and in other large cities in the United Kingdom."

Wednesday 20th.—Inspection and Demonstration in the District of St. George's, Hanover-square, at 2 p.m. (number limited), conducted by Albert Taylor, Chief Sanitary Inspector.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

The Municipal and County Engineers' Association having hybernated for nearly six months during the period, when all other professional and scientific associations are most active, has at last left the arms of Morpheus, and resolved to hold another meeting on the 19th inst. at Wimbledon, when our active friend Mr. Cooper, the Surveyor to the Council—than whom few members take a more lively and warm interest in the Association—has provided an interesting programme of visits. I hope to be able to refer to the meeting in the next issue of this journal.

It cannot be said that Mr. Long, the new President of the Local Government Board, is likely to depart from the traditional restraint which has hedged round the hide-bound practice of his predecessors, and we are not likely to witness any revolution in this department, which has earned, rightly or wrongly, considerable notoriety for red-tapeism and tortuous officialdom.

Recently Mr. Long was addressed on the housing question by the Secretary of the National Housing Council, and his reply was in the usual *non possumus* attitude, so dearly beloved by the Board. "In view," he states, "of the emphatic decision on the question of the extension of the period for the repayment of loans, which was arrived at in Parliament so recently as last year, I do not think I can hold out hopes that the matter is ripe for reconsideration by the Local Government Board."

It is a complaint that the building bye-laws of local authorities militate against the erection of cottages at suitable rents owing to the increased cost they indirectly causes, and Mr. Long on this matter writes that, "as regards model bye-laws, I am deeply impressed with the vast importance of throwing no unnecessary impediment in the way of those Local Authorities who are endeavouring to deal with the question of housing of the working classes, and I am therefore at the present time engaged in very careful consideration of the bye-laws of the Board, in order to ascertain whether alteration in any direction appears desirable, and if so, whether such alteration could be made without any unwise relaxation of those standards which are considered essential for the public welfare."

Now this sop to Cerberus will, I fancy, deceive few who are familiar with the subject. Moreover, it is the echo of a complaint which has been raised long ago by landlords. So long, however, as the complaint came from them alone, both Local Authorities and the Local Government refused to heed it. Now, however, when the matter affects Local Authorities themselves financially, a relaxation of the bye-laws is asked for. This Protean attitude of the Authorities is not edifying, and landlords have reason to denounce their waywardness and unjustness. There is, however, I am convinced, little hope that the bye-laws will be materially altered so as to cheapen the cost of houses, and the assistance of the Local Government Board in the matter may be set aside as a negligeable quantity.

One of the ablest articles on this subject is that by Lady Jeune which recently appeared in the *Times*. "The housing of the working classes," Lady Jeune writes, "is a national question, and it is one no longer to be left to municipalities and private individuals, but it is one which should be undertaken by the Government. There appears, however, only one way in which

a Government could deal with the work, and that would be by means of a Commission, constituted like the Charity and Ecclesiastical Commission, with powers to carry out the work on a large scale, and under such supervision it could be done well and honestly." The views of Lady Jeune, in my opinion, deserve the consideration of all persons interested in the engrossing subject, and I advise their careful perusal.

I SUPPOSE that Aldermen and Councillors on our public bodies deem it necessary on public grounds that deputations shall be appointed periodically to visit other towns on matters municipal. The purposes of such deputations are varied, and appear to extend. Whether the results obtained always justify the expenditure is possibly doubtful. But, after all, public representatives are entitled to some "confectionery," and this deputationising is one of the most favourite forms of taking it. It would be interesting to obtain a return of the amount spent by Local Authorities in the kingdom under this head. But I do not attempt to declaim against the practice, for the work of public representatives is rarely recognised or requited, and the educational value of municipal excursions to Councillors is considerable—their views are broadened; their acquaintance with a particular system or systems of municipal work is real, enabling them to arrive at an intelligent decision to the benefit of their constituents, and the methods, customs, and practices of other cities and towns are observed, some of which it is generally found may profitably be adopted. Just as "home-keeping youths have ever homely wits," so have home-keeping Councillors homely, hazy, and crazy ideas of municipal administration.

SUCH a charge could not aptly be made against the members of the Leicester Town Council, who last year sent a tramway deputation to the principal cities in the United Kingdom, and then to Brussels, Hamburg, Berlin, Vienna, Buda Pesth, and Paris—a truly royal trip, and managed on a liberal scale, as may be judged from the bill, which amounted to a sum of upwards of £700. The Leicester Councillors are to be envied. SENEX.

HYGIENE IN THEATRES.

THE question of the hygienic arrangement of theatres, says the Paris correspondent of the *Lancet*, is again to the fore, and at the recent congress on Theatrical Art the Society of Medical Officers to Paris Theatres was represented by a Committee of three. This Committee handed in a number of important resolutions and asked that a medical man should be upon the Superior Committee of the theatres, as, singularly enough, up to now no medical man has been upon that Committee. Certainly a member of the profession in question would be able to afford the Committee valuable advice upon questions of ventilation and the like when plans for the reconstruction or building of a theatre come before it. A medical man could, for instance, in the case of the Comédie Française have ordered the disinfection of the dressing-room of one of the artistes who died from phthisis and whose successor who took over the room also contracted phthisis and died in her turn.

M. Henriot, professor *agrégé* at the Faculty, and a member of the Committee of Hygiene, has undertaken a scientific inquiry into the defects of the Paris theatres from a hygienic point of view, and is taking samples for future analysis of the air from different parts of the house in the hope of discovering the microbes of the disease to which theatre-goers are liable. According to hygienic authorities, theatres are insanitary for many reasons, chiefly because they are badly ventilated and badly lit in so far that they get no sunlight. The ventilating fan is no good, for it raises clouds of dust, and is far worse in this matter than the feather broom. Then there is the floor upon which the audience frequently spits, and which when swept gives off clouds of dust which rise in the air only to fall down again. The most successful theatres, according to M. Henriot, are the most dangerous, for in them the audience stamps with enthusiasm and a quantity of dust is the result. M. Henriot's desiderata would be: (1) Better air and a natural system of ventilation. (2) Large windows through which the rays of the sun could enter. (3) All upholstery instead of being in velvet should be in leather, and no stuff drop scenes should be allowed. (4) All wooden furniture should be varnished, so that it could be washed over with a wet sponge. (5) The floor should be of some impermeable material, so that it could be washed, and should be covered over with a layer of fine gravel which should be swept off every day, and would carry with it all dirt, dust, &c. (*scories*), without the dust floating up into the air.

The Medical Officers of theatres ask for the installation in all theatres, cafés, concerts, and circuses of a *loge médicale*, that is to say, a room kept specially for the purpose, to which can be removed any actor or spectator who may meet with an accident or be suddenly taken ill. The room should be of fair size to enable the patient to be easily attended to, and must be ventilated by a window which opens easily. Its furniture should be only such as is necessary—viz., a sofa, a wash-basin, two or three hand-basins, some receptacle holding two or three litres of some antiseptic solution, and a cupboard for a few necessary drugs and dressings. There should also be a pair of scissors, a knife, a tongue forceps, a Pravaz syringe, and a night commode. The medical men who ask for this installation argue that in the great number of cases of accident cure depends upon immediate treatment by a medical practitioner, who must have the necessary articles for the application of such treatment.

ANNUAL REPORTS.

Hoxne (Essex).—In the annual report on the sanitary condition of the Hoxne rural district for the year ending December 31st, 1900, Dr. S. J. J. Kirby, Medical Officer of Health, calls special attention to the question of water supply, which demands serious consideration, for, being mainly derived from stored rain water, shallow wells, and ponds, it is liable to pollution. From the geological formation and configuration of the district it is found that, except in a few low-lying places, a supply of pure water can only be obtained at a great depth. Dr. Kirby therefore reports as follows:—"In every case in the future where old filters are taken up for the purpose of cleansing or renewal, or where new filters are laid down, I would strongly advocate the use of polarite instead of charcoal. Polarite is rapidly coming to the front as a more efficient filtrant than wood or animal charcoal, and, when once laid, is claimed to be indestructible, whereas charcoal after a time becomes worse than useless, as, instead of removing impurities from the water which passes through it, it gives back the impurities already removed, and it should be frequently renewed. In all cases where the provisions of the Public Health Water Act, 1878, are not complied with, I would earnestly urge upon you the necessity and advisability of enforcing them without delay. The rainfall might be more utilised than it is, and especially where the collecting surface is favourable, as from slate or tiled roofs."

Kingston-on-Thames.—The eighth annual report of the Kingston Medical Officer of Health (Dr. Beale Collins) has been issued. The birth-rate of 26·9 shows

a reduction upon the average for the last ten years, which was 30·3 per 1000; but the death-rate for the year stands at 14·06, which is below the average for the decennial period, namely, 15·1. These figures are based upon a population calculated at 36,604, as to which the Medical Officer remarks "this is little more than a mere guess, the correctness or otherwise of which can only be ascertained after the census." The zymotic death-rate of 1·2 per 1000, as against 2·1 for the last seven years, is a drop that is noteworthy. The only epidemic of the year was one of measles, which raged in the autumn. The Medical Officer puts the number of cases as "probably over 1000." It was "sudden and far-reaching in its onslaught," and he was unable to stay it by means that have proved successful on previous occasions. A few cases occurred in one school in the first week of September, and as no new cases appeared the school was not closed; but suddenly in the second week of October cases occurred simultaneously in three other schools, the disease spreading eventually to all the schools of the town. The Medical Officer's only suggestion for more fully grappling with outbreaks that may become epidemic in the future is "a more intimate supervision of schools and school children by Medical Officers."

Kinross-shire.—The following are the principal points in the annual report of Dr. T. G. Nasmyth, Medical Officer of Health of Kinross-shire. In his opinion the county is well supplied with water, especially at the eastern extremity, where the villages of Scotlandwell, Kinnesswood, and Balgedie are situated. Milnathort is provided with a gravitation supply. There are several farmhouses which are badly off for water. The question of how the hospital proposed to be erected by the county and burgh of Kinross was to be constructed engaged the attention of the Joint Committee on various occasions. The point was whether one of Messrs. Speirs' iron and wood hospitals was to be selected or one of a more permanent nature such as stone or brick. On the grounds of economy, with reasonable efficiency, the Medical Officer advised that an iron hospital would be satisfactory, but the majority preferred stone or brick. Plans have been prepared for the proposed hospital, but these have not yet been finally approved by the Local Government Board. There were fourteen cases of infectious disease notified in 1900, being only one-half that of the previous year. The death-rate (19·6) is the highest in the county for five years, but one-half of those dying were aged people, over 60 years.

Northallerton.—The annual report for the Northallerton district for 1900 shows a general death-rate of 14·72 per 1000, as against 15·26 for 1899; infant mortality 128, against 183; and birth-rate 21·8, against 23·29. The Medical Officer (Dr. Hutchinson) urges the systematic scavenging of the larger villages. Throughout last summer the nuisance and danger to health arising from Romanby Beck were as great as ever they were before Northallerton adopted a chemical system of sewage treatment.

Tottington.—In the course of his report for the year 1900 Dr. Poole (Medical Officer of Health for the Tottington district) says the returns of the local registrar record 126 births—47 males and 79 females—being at the rate of 19·96 per thousand. The deaths registered from all causes numbered 93—40 males and 53 females. Deducting deaths of non-residents and adding those who usually resided in the district but died outside, the deaths numbered 96, the death-rate being 15·20 per thousand. The infantile mortality was 63·50 per thousand births. There were 8 deaths under one year of age, 11 between one year and five, 7 between five and fifteen, 5 between fifteen and twenty-five, 39 between twenty-five and sixty-five, and 26 beyond the age of sixty-five years. The deaths from zymotic diseases were 8, being equal to 1·27 per thousand. During the year 68 cases of infectious diseases have been reported. A systematic inspection of the district has been made during the year, particularly the cowsheds and dairies. Dr. Poole says:—"The dairies are well kept and the farm premises are fairly clean. There have been no cases of zymotic disease traceable to a contaminated water supply. . . The water supply of the district has been more continuous than in previous years and has been of better quality. Water mains have been carried along Harwood-road (Chapel Ward) to houses hitherto unsupplied. . . The house accommodation for the working classes can hardly be considered adequate, but the houses in existence are fit on the whole for habitation, and there is with very few exceptions a sufficient amount of open space about their dwellings. Bye-laws relating to new buildings are in force in the district, but the section relating to the erection of buildings on 'tips' required to be enforced. No building ought to be erected on such tips until the expiry of at least two years." The population of the district in 1891 was 5768; and the population to the middle of the year was estimated at 6312.

Public Works.

SEWERAGE.

The Tarporley Urban District Council has resolved to carry out sewerage works at a cost of £4500.

An inquiry has been held at Hengoed with reference to the borrowing of £11,500 for sewerage works at Bargoed and Terpill.

Mr. Charles J. Lomax, Civil Engineer, of Manchester, has been instructed to report upon the sewerage and sewage disposal of Milford, Derbyshire.

The Blaby Rural District Council has sealed a loan of £2500 for sewerage works at Enderby. Application is to be made for the sanction to a loan for £7500 to carry out the Blaby sewerage, prepared by Mr. J. Turner, the surveyor.

The Tiverton Rural District Council has received a certificate from Messrs. Cameron, architects for the Thorverton sewerage works, for £185, due to Messrs. Hawking and Best, contractors, making the total amount paid to them £828.

It was stated at a recent meeting of the Newcastle-under-Lyme Town Council that, as the result of the recent inquiry concerning the Council's application for sanction to borrow £15,000 for a sewage scheme on the bacteria principle, the Commissioners recommended the extension of the proposed filter beds from 5000 to 6500 superficial yards. The Committee therefore recommended amended plans and estimates raising the cost to £17,225, to provide for the suggested extension. It was decided to apply for increased borrowing powers accordingly.

On the proceedings of the Rivers Committee recently coming up for confirmation before the Manchester County Council, Dr. Dreyfus stated that plans had been submitted for six acres of bacteria beds. When the additional beds were at work, which the Committee hoped would be very soon, they would then be able to purify by the bacteriological process about one-sixth part of the whole sewage of Manchester. The Surveyor had been instructed to prepare plans for an additional twenty-four acres, and when these were finished they would have thirty acres of bacteria beds at work.

The Dumfries Town Council has decided to purchase for £7000 the estate of Castledykes as a site for the proposed sewage works. The scheme of Mr. Allan Carter, C.E., Edinburgh, estimated at £17,500, has been adopted.

Colonel Slacke, R.E., held an inquiry at Rickmansworth last Tuesday to consider the proposal of the Urban District Council to obtain a loan of £31,000 for the purposes of sewage disposal and the construction of sewage and sewerage works.

At a recent meeting of the Lincoln County Council considerable discussion took place at the proposal of the Sanitary Committee to connect the effluent from the Bracebridge Asylum, together with a large volume of surface water from the hillside, with the sewers of the city. It was pointed out by the chairman of the Committee that this would mean that the engines at the Corporation Sewage Works would have to pump an additional 100,000 gallons, raising the total amount to 168,000 gallons daily. On the other hand. the step proposed would place the city water supply from the river source beyond the risk of pollution. Ald. E. Pratt spoke strongly against the proposal to take in the surface water, but Councillor Footman replied that this was the only practicable plan. The suggestion was adopted.

At a meeting of the King's Norton and Northfield Urban District Council, a long report was presented by the Public Works Committee on sewer ventilation. The special Sub-committee appointed to consider the matter had given careful consideration to most of the known systems, and having witnessed experiments and practical trials in the district, had found that most satisfactory results had been obtained by means of a simple water-spray used as an extractor at the base of a tall outlet shaft in conjunction with mica non-return inlets placed on the top of short columns. This system had been devised by the Council's engineer (Mr. A. W. Cross) as the result of experiments commenced at Loughborough, resumed at King's Heath, and lately demonstrated to members of the Sub-committee on a practical scale. This system the Sub-committee believed to be more efficient than any system of shaft or manhole ventilation, and more efficient and economical than any system worked by means of gas burners or water jets. The Committee approved the decision of the Sub-committee, and recommended that application be made to the Local Government Board for sanction to a loan of £3679, namely, £1812 for a scheme of improved sewer ventilation throughout the whole of the Council's sewerage system within the Tame and Rea area, £1130 for improved sewer flushing by means of automatic flushing tanks, and £827 10s. for the reconstruction of defective sewers. The report was adopted.

The Shipley District Council, after four years of anxious labour, was last week able to put into full operation the extensive and important sewage works. There was a large attendance of representatives of various Authorities at the formal opening ceremony, which took place at the works. Mr. Chas. B. Shaw (chairman to the Council), in accepting the gold-inscribed key, stated that the works would cost them altogether something like £75,000. The destructor works had cost them also £4000. He unlocked the door of the pump-house and sets the pumps in motion. The gentlemen present afterwards viewed the various works; the destructor, which was in full working order; the bacteria beds, into which the sewage was flowing freely; and the engine-houses. The destructor, which is of large capacity, and has been in operation for several months, was constructed by Messrs. Meldrum Bros., of Manchester. The furnace consists of a continuous hearth 19ft. long and 5ft. 6in. from back to front. There are four grates, only two of which at present require to be used. One large door will take bulky articles like mattresses. The destructor is at work, of course, day and night, and the two grates in use prove equal to the burning not only of all the Shipley refuse, but of large quantities from the Baildon district as well. The destructor has been specially constructed so as to generate steam freely in the process of burning the rubbish. The heat in the combustion chamber, often equal to a temperature of 2000 deg. Fah., passes into a Lancashire boiler, working at a pressure of 150 lb. After leaving the boiler the gases pass through the regenerator pipes, and enter the ashpits of the destructor at a temperature of 350 deg. Fah. The destructor will burn upwards of two tons of refuse per hour, and will generate steam sufficient for 350 horse-power, 1½ lb. of water being evaporated per lb. of the refuse. The steam raised provides the motive power for the pumping of the sewage, working an engine for breaking up "clinker," and generating electricity for the lighting up of the works. It is fully expected that when the destructor is working at its full capacity sufficient power will be produced to run the two turbine engines that have been put down for providing electric current for sale and for public lighting purposes. The clinker produced is used in the filtering tanks.

WATER.

In the House of Commons the Ilkeston and Heanor Water Board Bill has been read a second time.

The Doncaster Rural District Council intends spending £5000 in improving the water supply of Conisbrough.

The Shifnal Rural District Council has petitioned the House of Commons for leave to oppose the Water Bill, by counsel, when the Committee stage is reached.

A petition praying to be heard by counsel, against the Harrogate Water Bill in Committee stage, has been deposited at the Lords' Private Bill-office, on behalf of Mr. T. G. Lofthouse.

The Kelso District Committee of the Roxburgh County Council has instructed Mr. Harry W. Taylor, A.M.I.C.E., of Newcastle-on-Tyne and Birmingham, to report upon the water supply of Morebattle.

A Local Government Board inquiry has been held at Peasedown St. John with reference to the possibility of providing Peasedown with a proper supply of water. For some time this ecclesiastical district has suffered from lack of water, and notices are posted in the place, signed by the Medical Officer of Health, advising the inhabitants to well boil the water before they use it for drinking purposes. Peasedown is partly in the Clutton union and partly in the Bath union, and this probably has occasioned some delay in dealing with the subject.

At a meeting of the Tees Conservancy Commission, at Stockton, last week, it was reported that the Darlington Corporation proposed to seek power to erect additional pumping engines at Broken Scar, and that they would be capable of abstracting from the river Tees upwards of 2,000,000 gallons of water per day. Alderman J. Samuel said the Tees Valley Water Board was permitted to take 60,000,000 gallons per week out of the river, and when the new reservoir was completed it would have to compensate the river to the extent of 67,284,000 gallons, so that it was really putting into the river 7,000,000 gallons more than it was taking out. It was proposed to supply Hartlepool with some 22,000,000 gallons of surplus water. After further discussion it was agreed that the Secretary obtain particulars of Darlington's proposals, and take such steps as might be thought fit in the interests of the Commission. It was also decided to petition against the Tees Valley Water Board's Bill in order to secure a *locus standi*.

A Local Government inquiry has been held at Natland into an application to borrow £400 for a new water supply.

It is satisfactory to note that the Aberavon Town Council has agreed upon terms for the taking of an auxiliary supply of water from the Margam Urban Council. The coming together of the two Authorities on this matter has given much satisfaction, and complaints as to the dearth of water are now happily at an end.

The Corporation of Bridgnorth, the proprietors of the Staffordshire and Worcestershire Canal, Lord Wrottesley, the Earl of Dartmouth, and Colonel Kenyon-Slaney, M.P., have presented petitions to the House of Lords, notifying their intention of opposing the passage through Committee of the water scheme of the Corporation of Wolverhampton.

A public meeting has approved of the action of the Romford Urban Council in agreeing to lodge a petition to obtain the inclusion of certain concessions in the Bill of the South Essex Water Company. The expense is to be limited to £100, and if more be needed the ratepayers are to be again called together before it is granted. It was stated at the meeting that the Brentwood Urban Council and Billericay and Orsett Rural Councils are holding aloof, although they would benefit by the concessions.

At the meeting of the Spalding Urban District Council last week, it was reported that arrangements had been made with the Clerical, Medical, and General Life Assurance Society for a loan of £30,000, for the payment of the purchase of the Spalding waterworks, recently acquired by the Council, and for carrying out improvements in connection therewith. The loan is repayable in fifty years, the interest charged being at the rate of $3\frac{3}{4}$ per cent., and the half-yearly payment of principal and interest will be £644.

After a good deal of delay, and some additional expense, the Girvan Town Council has decided to proceed with the scheme of forming a second reservoir at Pinmacher, about a mile beyond the present waterworks, with a capacity of storing 15,000,000 gallons. The present reservoir has a capacity of 12,000,000 gallons, and that will give 27,000,000 gallons in all to Girvan. The source of supply is the same as the present, and no better water could be got anywhere. The Council has completed arrangements with the proprietor of the ground, Lieutenant-Colonel Dalrymple Hamilton, through Mr. Inglis, his factor, and Mr. Eaglesham, C.E., Ayr, who so skilfully completed the drainage scheme for Girvan, and also the present waterworks, has been instructed to prepare the necessary working plans for the new reservoir. The work will be proceeded with immediately. The estimated cost of the new reservoir and its connections is about £6000. A new filter has been constructed.

Opposition on the part of Local Authorities to the Barrow Water Bill, which was read a second time in the House of Lords on Friday and referred to a Committee, is deepening. The chief feature of the Bill is to take a water supply from the river Duddon, and to raise the level of Seathwaite Tarn, which flows into the Duddon by means of a dam. The Millom District Council opposes on the ground that the taking away of so much water will injure the tidal way and prevent vessels using the Millom pier. The Hodbarrow Mining Company also oppose, believing their channel and pier will be seriously menaced. The Askam Iron Company have given notice of their intention to appear against the Bill. The Dalton and Ulverston District Councils are asking for certain privileges and reduced water charges; otherwise they, too, will oppose. The Bootle Urban Council has given notice of opposition, while the Commons' Preservation Society ask for the insertion of a clause limiting the amount of land to be taken from Seathwaite Fell in the enlargement of the Tarn, and that a fence be erected close to the water's edge. Certain landowners and commoners are moving for a guarantee of their present rights and privileges.

LIGHTING.

The Omagh Gas Bill has been read a second time in the House of Lords.

The Hereford Gasworks Committee has received the sanction of the Lords of the Treasury to the borrowing of £1500 for the extension of mains.

The Scarborough Gas Company has given notice of their intention of opposing the North-Eastern Railway Bill when it reaches Committee stage in the Lower House.

A Local Government Board inquiry has been held at West Bromwich by Mr. H. P. Boulnois, with reference to the application of the Town Council for sanction to borrow £10,000 for electrical purposes.

The Finance Committee of the Stepney Borough Council has recommended the Council to borrow £122,200 for carrying out the electric lighting of the borough. The Electrical Engineer to the borough estimates that 100 miles of cable will be laid, twenty miles of trenching undertaken, and 280 arc lamps erected.

The Bill promoted by the Corporations of Hartlepool and West Hartlepool for the compulsory purchase of the undertakings of the Hartlepool Gas and Water Company has passed its second reading in the House of Commons. It will therefore now go into the Committee stage, in which the real struggle between the Corporations and the company is expected to take place.

On the recommendation of the Electric Lighting Committee the Southwark Town Council has accepted the tenders of Messrs. Siemens Bros. and Co., amounting to £4310, for the supply and fixing of another 400-kilowatt steam generator, and Messrs. Babcock and Wilcox, amounting to £3230, for the supply and erection of two new water-tube boilers.

A public meeting was held at Pinchbeck, near Spalding, last week, to consider the question of gas lighting of the village. The Spalding Urban District Council, which own the Spalding Gasworks, had been approached with a view to its undertaking the lighting of the village, and a deputation from the Council then attended. The estimated cost of laying the main was put at £665, the distance being two miles, and it was thought that the gas could be supplied to the village at 4s. per 1000 cubic feet, the charge at Spalding 2s. 6d. per 1000 cubic feet net, or if the village would lay their own main, the gas might be supplied at the same rate as at Spalding. A committee was appointed to consider the best method of procedure, and to take a house-to-house canvass to ascertain to what extent the gas would be taken.

It has transpired that as a consequence of the hard state of the money market, and the failure of the Special Committee of the District Council to negotiate a loan for the purchase of the undertaking of the Morecambe Gas and Light Company, the directors have submitted a scheme to the shareholders for the issue of mortgage bonds, bearing 4 per cent. interest, payable half-yearly, amounting to £141,000, the purchase price. Under this scheme the whole of the £141,000, with the exception of £214 1s., will be distributed amongst the shareholders, who will receive the following sums for each £100: 6 per cent. preference stock, £220; ordinary stock, £515; new ordinary stock, £413 13s. 9d. The directors also propose to pay the usual half-year's interest to the shareholders out of the interest received from the District Council during the past six months. The bonds are redeemable at par in five or three years.

The Corporation of Sheffield is prepared to receive applications for an issue of £500,000 Three per Cent. Stock, redeemable at par, on September 30th, 1925. The price of issue is £94 per cent., and interest is payable half-yearly. The present issue is to be applied in paying off loans bearing a higher rate of interest, and in raising funds towards carrying on works authorised by the local Acts and Local Government Board sanctions for extension of tramways, waterworks, electric light and power undertaking, street improvements, extension and erection of hospitals for the purposes of the improvement scheme made under the Housing of the Working Classes Act, 1890, and for the purposes of a recreation ground.

Sir Courtenay Boyle, permanent Secretary to the Board of Trade, presided on Thursday last at the Westminster Town Hall at the second sitting of the inquiry which is being held into the effect of the proposed alteration of the regulations for ensuring a proper and efficient supply of electricity. Mr. Percy Still, chief engineer of the Chelsea Electric Lighting Company, said the company supplied electricity on the three-wire system at both 200 and 100-volt pressure. They generated electricity at 1000 volts, and at sub-stations reduced it to 100 and 200-volt pressure. If the company were to have 100 and 200-volt customers they must have separate plant for each supply, or motor transformers on the consumers' premises. Either would involve very considerable expense. It was more expensive to supply at 100 volts than at 200 volts. The company had 2082 consumers, of whom 1516 were supplied at 200 volts, and 566 at 100 volts pressure; roughly, about 500 had changed from the 100 to 200 volts. Better terms were offered to consumers at 200 volts pressure. At 100 volts the charge per unit was 6d.; at 200 volts the maximum demand system of charge was in force, under which the price after a certain time was reduced from 6d. to 3d. per unit. This meant a reduction in the charge to the consumers of about £3000. The 100-volt consumers were being supplied at a loss, and the company were therefore about to raise their price by 1d. per unit. Mr. S. Baines, electrical engineer to the St. Pancras Borough Council, on behalf of the Westminster company, said the St. Pancras works were the first to supply electricity at the double pressure, or 220 volts. They experienced stubborn resistance to the change from 100 volts in four or five cases, and, as a fact, that had prevented the Authority from economically carrying out the change. They had to duplicate their mains in consequence of these four or five consumers. To induce consumers to consent to the change threats were made that the company would cut off their supply if they did not do so. The inquiry was again adjourned.

GENERAL.

Temporary buildings for cases of small-pox, at an estimated cost of £1200, are to be erected by the Leeds City Council.

As the small-pox epidemic in Glasgow has rather increased than otherwise, the Glasgow Corporation has agreed to establish a special vaccinating corps of 100 men to visit every dwelling in the eastern part of Glasgow and insist upon re-vaccination being performed.

An interesting note has been issued by the Medical Officer of Brighton in anticipation of his report for the past year, drawing attention to the very low mortality from typhoid at Newsholme. He says he has no hesitation in ascribing it to the warning publicly posted on the beach against the eating of oysters, mussels, and cockles from sewage-polluted sources. The sanitation of Brighton has so immensely improved that other causes of typhoid are rapidly disappearing.

The Leeds Town Council contemplates an expenditure of £15,000 in erecting baths and a library in York-road. Baths are also to be provided for the Bramley portion of the city at a cost of £8000.

The Commissioner of Public Health at Brisbane (Dr. Ham) is, we understand, preparing a set of model health bye-laws, which will be subject to alterations, to adopt them to the varying conditions in the different municipalities and divisions. The bye-laws will be based on those of the Local Government Board of England.

The Edmonton Urban District Council having applied for sanction to borrow £30,000 for the erection of a Council Chamber, swimming baths, and other buildings, the Local Government Board wrote saying that the Council had not adopted the Baths and Wash-houses Act. This omission was rectified at the Council's last meeting.

The Newcastle Sanitary Committee is in favour of employing female Sanitary Inspectors. At its last meeting it was decided to recommend the appointment of three—one for each of the three proposed divisions of the city. It was reported that in other large centres of population, such as Birmingham, Manchester, and Liverpool, the employment of women in the above capacity had been a success. The lady Inspectors will, if appointed, be in the Health Department, and under the direction of the Medical Officer.

Last week a special meeting of the Sanitary Committee of the Middlesbrough Corporation was held at the Middlesbrough and Port Clarence ferry. The barge and the wharf were examined, and the other appliances to be used in connection with the barging-out scheme were also inspected. It was decided that a portion of the wharf should be covered with iron plates, and that at high tides the night-soil should be tipped there. It will then be shovelled into the barge. The Committee also decided that the general public, if there was any accommodation, should be allowed to tip rubbish into the barge at a charge of 6d. per load.

Reporting on a case of overcrowding in the Truro district, Mr. E. W. Tonkin, the Sanitary Inspector, stated that at Creegbrawse, near Chacewater, a family consisting of man and wife, three sons, aged respectively 23, 21, and 15, and a daughter aged 18, occupied one bedroom 15ft. by 12ft., and 6ft. 4in. high, giving a total of 1170 cubic feet. The room was partly divided by a screen, and the gross measurement reduced by the space occupied by furniture, and as the minimum air space was 1500 cubic feet, this was a bad case. The father said he could not get a larger house, but there was no reason why the younger members of the family should remain at home.

A well-attended meeting of the Church Sanitary Association was held at the Westminster Palace Hotel last Thursday, when the chair was taken by the Archdeacon of St. Asaph. The Chairman said sanitation was one of the problems of the day. As a rule the clergy were admitted to every house in their parishes, and so might be of very great use in bringing the question to the fore. Dr. Schofield moved the first resolution: "That it is desirable that preachers and teachers inculcate the obligation of endeavouring to secure for all pure air, pure water, abundant light, and wholesome environment." The Rev. Septimus Buss seconded the resolution, which was carried. A second resolution, "That it is desirable that the society organise and develop local centres," was proposed by Dr. Christopher Childs, seconded by the Rev. F. Bailey, and carried unanimously. Mr. Bailey suggested that Leeds should be first approached with regard to courses of lectures on sanitation, and as a likely starting point for a local centre. Lady Jeune moved the third resolution: "That fresh legislation is necessary in the direction of securing the better housing of the working classes." The resolution was carried *nem. con.*, and the proceedings closed.

The Warminster Urban District Council proposes borrowing money for a new technical school, works of sewerage, and water supply.

The Sanitary Committee of Middlesbrough Corporation has decided that provision shall be made in the next estimates for the employment of a woman Sanitary Inspector for the borough.

The Medical Officer to the Gainsborough Rural District Council report last week three adults suffering from diphtheria in one house at Harpswell, where there was a total absence of drainage. Some time ago the Medical Officer advised that a large cellar to a house at Stockwith be filled up on account of its being filled at times with a mixture of sewage and Trent water. There was a case of fever in the house at the time, and he reported a further case of typhoid in the house at present. The Surveyor intends to disconnect the sewer from the people altogether. But this is not sufficient. The District Council must insist on proper drainage being provided, or the place will remain a fever-breeding preserve.

At a recent meeting of the Llanelly Borough Council a petition was presented from the inhabitants of the New Dock district protesting against the Old Coke Works as a site for an infectious diseases hospital on the ground that it was in immediate proximity to inhabited dwellings. The Chairman explained that all that they had done was to instruct their Surveyor to make arrangements with the tenant of the Old Coke Works to vacate the premises at a day's notice, provided that there was an outbreak of infectious disease. Mr. Joseph Williams proposed that the Old Coke Works should not be used as a hospital for infectious disease. Mr. Gwilym Evans moved an amendment that while of opinion that it was not a suitable place, the Old Coke Works should be used in case of emergency. On being put to the meeting seven were for and seven against, and the Chairman gave his casting vote for the amendment.

The Walthamstow Urban Council has erected a model sanatorium for infectious cases with its own workmen, and without seeking any outside assistance whatsoever. The hospital, which was opened on Saturday, stands in five acres of ground at Chingford, and is constructed in blocks, 40ft. apart, so that at any time extensions can be made without disturbing the patients, for whom there are forty-six beds. Although the death-rate in Walthamstow is stated to be as low as in any other district in the metropolis, some 300 cases of diphtheria, and 400 of scarlet fever are met with every year. The need, therefore, for an isolation hospital was urgent, and the fact that the institution was erected by town labour is a testimonial to the enterprise of the local Council.

Mr. W. Price-Heywood delivered a lecture at Clayton last week on the "Slums of Manchester, and the Measures that would tend to their Improvement." He spoke of the necessity for sweeping away the slum areas in the centre of the city, and argued that the owners of insanitary slum property were no more entitled to compensation than the man whose unsound meat or impure foodstuffs were seized and destroyed. As remedial measures for the present evils he advocated the granting to municipal bodies of much greater powers than they at present possess for acquiring land upon which to erect suitable housing accommodation for the poorer classes without the necessity for excessive rentals or the imposition of heavy burdens on local rates. Cheapened train and tram services and the decentralisation of industries were amongst the other topics he touched upon, and Mr. Price-Heywood briefly outlined the scheme for starting in the South of England a "garden city," the factories and workshops of which are to form a huge circle enclosing an area for residential purposes, to be so laid out as to create a "garden city" in the literal sense of the term.

At Whitechapel's great hospital—the London—last year were treated 12,746 in-patients, on whom 9000 operations under anæsthetics were performed. So rapidly is the work growing that great extensions have been made necessary, and to meet all requirements it has been decided to expend the huge sum of £370,000 in the next few years.

A Special Committee of the Glasgow Corporation met on Tuesday to consider the question of municipalising public-houses. It was decided by a majority to recommend that the Corporation should generally approve of the principle, and that application be made to Parliament for powers, the profits to be devoted to public purposes.

Up to the middle of February influenza has this year been almost quiescent—indeed, for several weeks it had almost reached the vanishing point. The changes of atmosphere and of constitution, which accompany the advent of spring, has stirred up a little the latent germs of the malady, which during the past fortnight has made its presence felt insidiously. Last week the deaths directly attributable to it rose to thirty-five, or three times the number recorded three weeks ago. These figures are infinitesimal compared with the fatalities which marked the progress of this scourge in the early months of previous years; but they are sufficiently ominous to warn those who feel influenza coming on to consult their doctor at once and mitigate as far as possible the attack. Otherwise the Registrar-General's returns may be augmented by many victims. The general health of the metropolis remains fairly good, the only disquieting feature, in addition to the influenza, being the prevalence of pulmonary and bronchial complaints, due in the main to neglected colds. The death-rate throughout London was 20·9. Brighton's was 19·2, Croydon's 15·5, and West Ham's 16·9, while Plymouth headed the list with 38·2.

The Local Government Board inquiry into the proposal of the Leeds Corporation, under the Housing of the Working Classes Act, to improve the "Quarry Hill insanitary area," was resumed last week by Mr. R. H. Bicknell, M.I.C.E., at Leeds. The cross-examination of Dr. J. S. Cameron, the Medical Officer of Health, was taken up by Mr. Walter Tempest. He wanted to know something of the people displaced by the scheme in the Quarry Hill district, and what was to become of them. The rents of the houses in the district, Dr. Cameron said, ranged from 1s. 6d. and 2s. to 4s. and 5s. per week. Mr. E. B. Martin, Assistant City Engineer, said he was appointed by the Corporation to take charge, under Mr. Hewson, the City Engineer, of the schemes dealing with insanitary areas. He put in several plans, and went on to give particulars of the property in the area affected by the inquiry. The total population of the area was 10,577, and of that number 9234 belonged to the labouring classes, 254 had no fixed abode and resided in common lodging-houses, and 402 had not houses of their own and rented furnished rooms. Taking a half-mile radius from the outer boundary of the scheme, he found there were 214 empty houses, which, as regards rent, were suitable for occupation by the labouring classes. The vast majority of these houses were in a sanitary condition; at least, they were infinitely better than those in the area. Outside that half-mile and within a radius of a further half-mile there were 300 more houses available, making 514 within a mile radius. He fixed 6s. per week as the maximum rent of a house suitable for the working class. By taking the total area covered by highways (88,559 square yards) in the area, and dividing it by the total length (9853·15 yards) he found the average width of the streets in the area was 26ft. 11½in. The minimum width of streets required in Leeds was 36ft., while the Local Government Board's model bye-laws required a street to be not less than 42ft. in width.

PERSONAL.

Mr. W. T. D. Allen has been appointed District Medical Officer of the Liverpool union.

Dr. Jackson has been reappointed Medical Officer of Health for Carnforth at a salary of £20 per annum.

Mr. John Newby, of Newcastle-on-Tyne, has been appointed Sanitary Inspector for Southwark, out of twenty-six applicants.

Mr. John Barclay, Assistant Sanitary Inspector, Aberdeen, has been appointed Sanitary Inspector for Musselburgh, at a salary of £100.

The Chief Inspector of Factories has appointed Dr. Gordon to be Certifying Surgeon under the Factory Acts for the Towyn district of Merioneth.

Dr. A. Wright has been reappointed Medical Officer of Health for Romford, at a salary of £90 per annum, and Mr. Cornell Sanitary Inspector, at £130 per annum.

Mr. J. E. Parker, C.E., of Blackhill and Newcastle, has been appointed Engineer for the intended scheme of sewerage and sewage disposal for the lower portion of Benfieldside.

The resignation of Dr. J. H. Crocker, who has been appointed Medical Officer of Health for Richmond, Surrey, has been accepted with regret by the Manchester Port Sanitary Authority.

The Health Committee of the Rochdale Corporation has decided to increase the salary of Mr. Lee, Meat Inspector, from £91 to £104 per annum, and that of Mr. Field, Assist. Inspector, from 30s. to 33s. per week.

Dr. T. Orme Dudfield, the Medical Officer of Health for Kensington, who was granted an increase of salary, from £800 to £1000 per annum, on condition that he gave up his appointment as District Medical Officer under the Board of Guardians, has decided to waive his claim for superannuation allowance from the latter body.

His Majesty the King, the Sovereign head and patron of the Grand Priory of the Order of the Hospital of St. John of Jerusalem in England, has graciously accepted the office of patron of its ambulance department, the St. John Ambulance Association, and has been succeeded in the office of President by his Royal Highness the Duke of Cornwall and York, K.G., Grand Prior of the Order.

REVIEWS.

Lockwood's Builder's, Architect's, Contractor's, and Engineer's Price Book for 1901. Edited by Francis T. W. Miller, A.R.I.B.A. London: Crosby Lockwood and Son. Price 4s.

The present edition of the above well-known work of reference may be as strongly recommended to our readers as any of its predecessors. The new edition bears marks of careful revision, and it will be found that the various prices and costs given are well up to date. It appears to us, however, that the portion of the work which is devoted to "Drainage" requires some revision and amplification. The recommendation that ventilation pipes should be "finished at the top with a cone or with one of the numerous extractors," for instance, is hardly in accordance with the practice of advanced sanitarians. Iron drains are now also so frequently used that some reference might be made to them, and their prices given. Prices of manholes, drain bags, and various other matters might also be usefully included in order to render this section as useful and valuable as others in the book.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2117.—Mortality Rates in Thirty-two Great Provincial Towns for 1900.—"M. O. H." writes:—"I wrote you a short time ago for particulars as to how and where to obtain the mortality rates in the thirty-two great provincial towns in the kingdom, when you were good enough to inform me that such particulars would be supplied by the Registrar-General, Somerset House, W.C. I have pleasure in enclosing you herewith a copy of his reply."

Answer.—We are indebted to our esteemed correspondent for sending us the information. Dr. Tatham, the Statistical Department, Somerset House, writes:—"I am desired by the Registrar-General to inform you that he does publish death-rates for the aggregate of the thirty-two great provincial towns. The estimated populations of these towns in 1900 was 7,021,167, and the births, deaths, and deaths from the principal zymotic diseases summed from the weekly returns amounted to 209,456, 140,280, and 18,872 respectively. These figures are equivalent to annual rates of 29·9, 20·0, and 2·69 per 1000 living.

2118.—New Buildings: Inspection of by Different Inspectors.—"H. W." writes: "Your opinion is asked as regards the procedure of a Sanitary Authority who employs a building Inspector to supervise new buildings during construction and test the drains by the hydraulic test. Although this Inspector certifies the whole of the work, yet if the owner of the property requires a separate certificate for the drainage only, the building Inspector cannot grant it and another official who has not seen the actual construction is sent to test the work. Now I have never known the second official approve what the first official has passed without an alteration of some kind having to be carried out by the owner. My point is, should not the same official certify who has supervision of the work while in progress?"

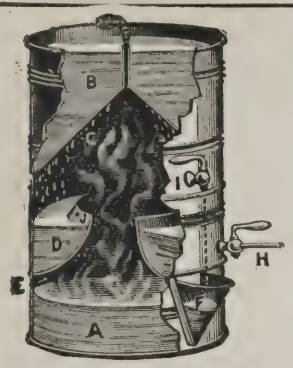
Answer.—We do not feel we should be justified in condemning the system referred to by the querist in the absence of further information. The Local Authority probably have good and sufficient reasons for adhering to it. But our experience of Local Authorities is that aggrieved ratepayers or owners—providing their complaint is reasonable and well-founded—can always secure proper consideration. Moreover, discontented ratepayers have their remedy at the polls, and builders and houseowners usually know how to exercise their influence at such times.

2119.—Sale of Food and Drugs acts: Obtaining Samples of Milk.—"Hygiene" writes:—"I should feel obliged if you will inform me if it is necessary to ask for "new milk" when purchasing samples under the above Acts. Ordinary customers ask for "milk." Consequently, if new milk is asked for, the milk-sellers in the district know it is for analysis, and generally answer in such a way that the sample is not sold, to my prejudice."

Answer.—In Lane *v.* Collins, 14 Q.B.D., 93; 49 J.P., 89; where an Inspector who asked for "milk" was supplied with skimmed milk, which by reason of being skimmed was deficient in butter fat, and proceedings were instituted against the vendor under Sec. 68, the Sale of Food and Drugs Act, 1875, it was held that no offence was committed under this Section. It is, however, submitted that proceedings may be successfully instituted under such circumstances under Sec. 9 of the Act of 1875. Moreover, if the receptacle containing skimmed milk does not contain a label thereon, as required by Sec. 11 of the Sale of Food and Drugs Act, 1899, the vendor will be liable to the penalties provided under this Section. The querist should be aware that it is not compulsory that he should personally obtain the samples. These may be obtained by a deputy and handed to him. See Horder *v.* Scott 5 Q.B.D., 552; 44 J.P., 520; 795; Smith *v.* Stace, 45 J.P., 151. We advise, however, that if "new milk" be required this be asked for.

2120.—Sewage Disposal for Isolated Group of Houses.—"Sanitarian" writes:—"I should be glad if you would give your opinion as to the best practical method of disposal of the sewage from twenty pairs of cottages each side of the road, as sketch herewith. This is outside the Local Authority's district, consequently there is no public sewer. Two said drains will run parallel with the road to a field below. What would you suggest should be done with the sewage after it reaches this point?"

Answer.—The sewage may be treated biologically in tanks and bacteria beds, or by bacteria beds alone, at a comparatively small cost. The querist should obtain Thudichum's "Bacterial Treatment of Sewage," price 1s. 3d.; Martin's "Purification of Sewage by Bacteria," price 6½d.; and Adams' Local Government Board Requirements as to Bacterial Sewage Systems," price 2s. 6d.,



DRINK PURE WATER

Physicians say 95 % of our countrymen and women fill their system with poison, lime, acid, minerals, old age matter, contained in raw water. Debility, nervous afflictions, skin and blood diseases, malaria, typhoid fever, are often the direct result of drinking impure water.

THE **'GEM'** PURE-WATER STILL is a perfect, hygienic, automatic apparatus, which will make the foulest water clear and sparkling, and remove all mud, lime, sewerage, microbes, and poisons. It is better than the most expensive filter, and should be used by all who value health. Send for pamphlet containing valuable information, or order a Still at once. AGENTS WANTED.

Call and see it in operation.

from which he will be able to obtain information as to the principles of the system referred to. Any of the books named may be obtained post free at the prices named, from the office of this journal.

2121.—INFECTIOUS DISEASE: REMOVAL OF PATIENTS TO HOSPITAL.—"J. M." writes:—"Will you be good enough to inform me what is the meaning of the term 'a convenient distance of such district,' as used in Sec. 124, of the Act of 1875, which refers to infectious hospitals and removal of persons thereto? (2) What is meant by the words 'and is without proper lodging or accommodation,' and who is to decide as to the sufficiency of such lodging. (3) In a district where the nearest hospital is eight miles distant, would the Medical Officer be justified in directing the removal of a patient who is suffering from an infectious disease—say, diphtheria—to such hospital, and when only a very defective ambulance is provided?"

Answer.—It is difficult to give the exact meaning of the term. As to what is a convenient distance, this will depend partly upon the means of access to such a hospital. (2) The term "without proper lodging and accommodation" has been held to apply where a patient, though living with his parents, and was provided with proper nourishment, and medical attendance, could not be isolated in his parents' dwelling-house. See Warwick *v.* Graham, Q.B.D. 15 T.L.R., 410 (1899); 107 L.T., 163 (1899). (3) It is impossible for us to pass judgment on the action of the Medical Officer of Health with the information before us. Only another medical man who had visited the case at the time of removal could be competent to give an opinion. The discretion of the Medical Officer of Health is absolute in such a case.

2122.—INSUFFICIENT WATER-CLOSETS: HAND FLUSHING.—"Sanitas" writes:—"In this town a very large number of cottages are without flushing cisterns and water supply to the w.c.'s In houses where enteric fever has occurred the Local Authority on the report of their Inspector of Nuisances has called upon the owners, under Sec. 36 of the Act of 1875, to provide a proper water supply and flushing apparatus. The water company, which is a private one, have, however, made regulations, approved and confirmed by an arbitrator duly appointed by the Corporation and the water company under seal, one of which states that in tenements not exceeding £20 per annum rateable value every water-closet to which water supplied by the company is laid on, shall have a waste-preventing apparatus of the prescribed kind so constructed as not to be capable of discharging more than two gallons at a flush, and every such water-closet now existing and not having such waste-preventing apparatus, shall either be altered to conform to this regulation, or shall have the water supply cut off from it, and shall be flushed down by hand. Inasmuch as these regulations are all under £20 rateable value, can the Local Authority in face of these regulations enforce the laying on of water and the provision of flushing apparatus under Sec. 36 of the Act of 1875? If not, would bye-laws made under Sec. 23 of the Public Health Acts Amendment Act, 1890, empower the Authority to enforce the same. The arbitration in the above case was made after the passing of the Act of 1875."

Answer.—The regulations referred to by the querist are regulations as to water supply house fittings, &c., issued by the private water company with the approval and consent of the Corporation. Such regulations do not, however, supersede the provisions of the Public Health Acts. The w.c.'s are insufficient for the purposes of Sec. 36 of that Act, being without flushing apparatus, and the Local Authority may by notice served under that section require the provision of a sufficient flushing apparatus. See Sherborne Local Board *v.* Bogle, Q.B.D., 18th March, 1880, 46 J.P., 675. The Local Authority may, by bye-law under Sec. 23 of the Act of 1890, require the provision as regards existing closets of a sufficient quantity of water for the proper flushing thereof, and enforce the provision of cisterns. In such case it is not necessary to prove the insufficiency of the closet.

CRAIG'S WHITE GLAZED FIRE-CLAY SINKS

On White Glazed Fire-Clay Supports.

In appearance nearly equal to Porcelain, which they greatly excel in strength and durability. Admirably adapted for use in Kitchens, Sculleries, Butlers' Pantries, Laboratories, &c. Extensively used in houses of the better class, and in many important buildings throughout the country during the last thirty years.

Adopted by H. M. Board of Works, H.M. Commissioners of Prisons, &c.

THE SANITARY INSTITUTE.

VENTILATION.—SUCCESS AND FAILURES OF PRESENT METHODS.

A SESSIONAL meeting of the members of the Sanitary Institute was held on Wednesday, the 13th inst., at the Parkes Museum, Margaret-street, W., Mr. J. Osborne Smith, F.R.I.B.A., presiding over a good attendance.

Dr. C. CHILDS, M.A., M.D., opened a discussion on "Ventilation: Success and Failures of the Methods at present in Use." He said that the importance of the question, the complexity and uncertainty of ventilation, and the difficulty of forming opinions, were sufficient reasons for the Institute endeavouring to promote a distinct knowledge with regard to the true nature of the problem and the practical ways of solving it. What was required was the replacing of vague notions with concrete and definite views. Proof of the need for study of the subject could be found in the recent code of regulations issued by the Education Department, which recommended 2½ square inches extraction per head in the upper part of the room, without any definite instruction as to whether the air was to be extracted by the natural process of ventilation, whether by mechanical force, or whether the air was to be exchanged once or ten times in the course of an hour. Much useful information had been obtained by various competent observers, and this information ought to be collected and formulated and treated on a scientific basis. Professor Carnelly had carried out particularly exhaustive inquiries, and advantage ought to be taken of his experiments, particularly in regard to schools. One definite question he desired to raise, viz., whether the plenum system was the best system for schools where the floor space is practically limited to a minimum of 10 square feet per head. The question of the applicability of the plenum system to hospital ventilation also deserved consideration; but this question he thought was at present *sub judice*. Now successful ventilation was that which provides a supply of air (1) sufficient in quantity; (2) of proper quality; (3) of a suitable degree of temperature and humidity; (4) properly distributed in equal proportion to each individual; (5) without producing any discomfort or feeling of draught, or any gradual though imperceptible depression of health; (6) with provision for complete removal of the air which has been exhaled by any individual; (7) in such a way as to maintain fully bodily and mental vigour; and (8) in such a way that the whole process is reasonably practicable and economical. There was also a necessity for considering and arranging the processes of warming and lighting enclosed spaces at the same time with that of ventilation. Frequent failures arose because these three processes were carried out by different individuals without concerted action. The plenum system was that by which air was driven by mechanical means through ducts, shafts, and inlets into and through rooms, and finally out of the building through specially-constructed outlet shafts, the incoming air being warmed in cold weather. The advantages claimed for this system were that the air could be obtained from selected sources; it could be warmed, washed, and filtered; it could be distributed to all parts of the room, and to each individual; the air could be changed ten times in an hour without producing discomfort; a marked improvement could be effected in the alacrity and mental vigour both of scholars and teachers, as compared with the results produced by other systems; and the air contaminated by respiration, exhalations from skin, clothing, &c., was completely driven out of the room. The disadvantages of the system were the dependence of the whole and every part of the system upon individual intelligence, care, and vigilance, and consequent liability occasionally to partial failure or even complete breakdown of the process; and the large initial cost of installation. On the whole the advantages claimed for this system, particularly in the case of schools, had been verified. Dr. Childs then dealt with the so-called natural system of ventilation, viz., the propulsion of air through the agency of atmospheric currents, aided by the warmth of the bodies of inmates, or artificial heat, open fireplaces, stoves, hot-water pipes, &c.; the "exhaust or vacuum system," which extracts air by the agency of heat or mechanical means, such air being replaced by currents through inlets in the outer walls; Dr. Glover Lyon's system for distributing the incoming air in even and regular columns across rooms, the direction and distribution being controlled by mechanical means; and the "open-air system," viz., free perflation through open doors and windows. The conclusions arrived at by Dr. Childs were for the ventilation of school-rooms having less than 16 square feet floor space per head. The plenum system is by far the best, and should be instituted wherever it is practicable; for school-rooms which had a larger area than 16 square feet floor space per head, it might be preferable to arrange for so-called natural ventilation, but he still regarded this as an open question; exhaust systems, and as combined with propulsion systems, are to be condemned; in cases where the plenum system is found to fail, such failure is due to some defect in the installation or manner of working it; for the ventilation of hospitals having a cubic space of 1000 to 2000 square feet per head, the question remains to be decided whether the plenum system is the best, or whether free ventilation by open windows can be contrived without production of draughts or too much lowering of the temperature. With regard to domestic ventilation, for this provision should be made for constant and free ventilation by halls, staircases, and passages, bedrooms should be freely and constantly ventilated by open windows, these being closed only from sunset to bed time; sitting rooms may be freely ventilated during occupation without discomfort by widely-opened windows. For overcrowded places like churches, concert rooms, theatres, and law courts, propulsion, aided by extraction and some modification of the methods advocated by Dr. Glover Lyon, would probably prove most successful.

A long and interesting discussion ensued, the speakers being the Chairman, Dr. Shelley, Dr. Steigman, Mr. Henman, Dr. Glover, Mr. Key, Mr. A. H. Ough, and Mr. McGorman. Votes of thanks to Dr. Childs and Mr. Osborne Smith closed the meeting.

SOCIETY OF ENGINEERS.

NOTES ON CERTAIN DETAILS OF DRAINAGE CONSTRUCTION.

(*Concluded from page* 226).

THE following is the discussion on Mr. Jensen's paper:—

THE CHAIRMAN, in proposing a hearty vote of thanks to Mr. Jensen for his paper, said that the author had given them some very interesting details, which he hoped would lead to a valuable discussion. The remark that perfect details made a perfect whole was more applicable to drainage work than to any other work. Unless every detail of a drainage system was absolutely perfect that system would be utterly at fault. The chain always broke at the weakest link. One point which was always in his mind had not been touched upon, viz., air inlets, which were equally important with air outlets. He did not agree with Mr. Jensen's implication that a good design should cover scampered work; on the contrary, a good design should lead to the prevention of that great evil in all drainage work, scamping.

Mr. W. D. SCOTT-MONCRIEFF said there was a

personal interest attaching to the paper so far as he was concerned, because Mr. Jensen was an old pupil of his. It would be the general opinion that the paper did him great credit, it having the good qualities of being thoughtful, painstaking, and moderate. Mr. Jensen might be taken to have proved his case in each of the points he had raised. The distinctions between most of the diagrams were sufficiently obvious as not to need explanation. He would, however, like to make some remarks on the general bearing of the paper, not upon the experience and daily practice of experts, but upon the interests of the community as a whole. The average layman in this country had been dependent upon the advice and the assistance which had been afforded him by professional men in the matter of domestic sanitation. It would be interesting to have some statistics as to the vast sums of money which, as a matter of fact, had been spent in London during the last twenty-five years in the domestic drainage of that great city. No doubt the expenditure amounted to many millions. Now, the expert—the engineer—and, in the majority of cases, also the contractors, they had a very clear conscience indeed with regard to the way in which the great bulk of that money had been spent. In the early days no doubt some of that money was spent badly and indifferently, and certainly not so well as we with twenty years' experience at the back of us know that it ought to have been spent. Mr. Jensen's remarks were of much interest to the people who had spent these vast sums of money in improving sanitary appliances in their houses, because the more open questions there were in these matters the more expense would they incur. Hence this paper could be looked upon as exceedingly opportune. Looking at the community as the employer of the profession, the most interesting part of the paper dealt with the question of outlet ventilation, but that did not disparage either the importance of inlet ventilation or the minor details which had been discussed. The case of the school quoted by Mr. Jensen was not very creditable to the powers that be, and it was not often that an expert specialist was met with such a *non possumus* as he appeared to have been on that occasion. He thought that there were many districts in London where there was such a number of ventilating pipes terminating about the same level that on a still day there must be created a layer or strata of contaminated air on the plane, roughly speaking, of these vent terminations. This raised a question of great importance; the obvious means of preventing the dangers arising from these conditions is that the drains themselves should be so constructed and the conditions which create these objectionable gases should be minimised, and this could only be done by having the minimum-sized diameter of drain and the maximum available flush of water, unless some oxidising agent is used to prevent the danger. He thought, however, that it was wonderful that so much had been done in the last twenty years in the way of taking drastic measures to force the community to adopt sanitary precautions. He remembered the first case of the adoption of the cardinal principle of disconnection and trapping which was carried out by Dr. Fergus many years ago in Glasgow. The whole sanitary superstructure of the present day had been raised on practically that simple principle. With regard to Dr. Alessi's experiments, he believed that these had been somewhat disparaged, though the reason of this was not at all clear. As those experiments were of great importance he thought they ought either to be confirmed or disproved by repetitions of the experiments by competent bacteriologists.

Dr. Shirley Murphy, Medical Officer of Health to the London County Council, said that the subject was one of almost so entirely an engineering character, that the medical man could hardly be expected to pass an opinion. He had heard Mr. Jensen's paper with interest, because, as was known to some of them, he was interested in certain by-laws of the London County Council which they hoped at no great distance would be in force, and those by-laws imported some of the points which had been touched upon. What had struck him forcibly whilst listening to the paper was the extreme difficulty of getting in drainage work such complete workmanship as would ensure the continuity of a drain. As one of a committee of an infectious diseases hospital, he could say that fifteen years ago the whole drainage of the institution was re-laid under most competent supervision, the drains were laid on concrete and tested, and found perfect when completed. Recently something went wrong, and it was found that now the whole system of drainage was practically faulty, yet the work had been exceedingly well done a few years ago and was then expected to last a lifetime. He would like to elicit some expression of opinion as to the life of good earthenware pipes thoroughly well jointed, and particulars of the life of a drainage system properly constructed. At present there seemed to be much doubt about the matter, and he almost was in despair, and certainly would be if laying good pipes on concrete and properly joined was a failure.

Mr. Silcox thought the Society was to be congratulated upon having had Mr. Jensen's paper. Broadly they could all agree with most of the views he had expressed. The difficulty in these matters was, of course, to get one's clients to undertake the work on the best possible lines because of the cost. The chief points to be kept in mind in regard to ventilation pipes was to have them as large as possible; he would have a large iron pipe with the risk of rust rather than a smaller lead pipe, which he thought was not so effective. He invariably used iron ventilation pipes, enamelled inside, and this got over the difficulty of rust, and if the pipes were carefully handled they would last a long time. As to their actual life he was, of course, not prepared to speak. The rust chambers referred to by Mr. Jensen were easy to make and easy to clean. On the whole he was inclined to favour larger pipes of iron rather than restrict the size to bring down the cost of lead. Most cowls were efficient under certain circumstances, but all sorts were liable to get out of order. He much preferred a perfectly plain wire guard over the top of an open pipe; the passage of air over the top caused a draught nearly as efficient as a patent cowl, and there was less danger of obstruction. Mr. Jensen's suggestion that the bends of ventilating pipes should be enlarged in sectional area appeared to be an excellent one, though he had never adopted it. It was used in connection with steam pipes, especially for heating purposes, and gave good results. Such enlargements might be difficult to get, for he had never seen any made. Air inlets was a difficult subject, and of equal importance to air outlets, because the difficulty was to prevent an air inlet becoming an air outlet. Certain flaps were said to prevent the danger of a sudden down-draught, but as they easily got out of order, they were more or less a failure. They were really brought to this, that the air inlet must be put in such a position that if it did become an air outlet it would not do any harm. This was most difficult to attain, especially in town houses, where the inlet might probably have to be put in a small back yard or front garden, or else carried up by means of pipes along the face of the building; if carried up as high as an air outlet, theoretically it became of equal value to the outlet, and the cost would be excessive. If the pipes were made short. then there was the danger of the inlet becoming an outlet in the neighbourhood of a window. Personally, he preferred to omit them altogether where they could not be provided with safety. With regard to the case mentioned by Dr. Shirley Murphy, it seemed to him there ought to be some explanation which would have been obvious to the person who examined the system. The concrete

might have been laid on a foundation which had sunk, and so caused the pipes to crack, or there might have been exceptional vibration. He had known pipes to break from such a cause, especially when there was a soft or yielding substratum in the neighbourhood of heavy traffic. He had examined many drains, but had never seen good earthenware pipes broken or showing signs of decay unless there was some explanation which was fairly obvious. His opinion of the life of an earthenware pipe was satisfactory.

Mr. Angell (Bermondsey) said that he understood from Dr. Shirley Murphy that there were some local circumstances which had caused the pipes to fail, but he thought it was a question to which they might give their serious attention. The draining of the subsoil would cause a subsidence, and although the pipes might be encased in concrete the pipes would be cracked. With regard to the use of gasket, he admitted that the gasket would perish in course of time and leave a cavity, but would not the sewage be prevented from taking its place by the fact that the spigot was driven right in solid to the socket? This he believed was always an instruction to foremen on drainage works. It was also possible that all the cement would not be removed from the pipes in the way described, leaving the interior of the pipe coated. This would be worse than sewage in the joints, and had been their experience in Bermondsey. In course of time a stoppage was created. He thought there was a tendency in sanitary as in other matters to indulge in a little faddism. Reference had been made to cementing manholes instead of using glazed bricks, but surely if the manhole was built with bricks that are rough on the beds, or, better still, with blue bricks, and built in cement, the manhole would be absolutely water-tight. He did not like cementing manholes; the cement might crack and a considerable amount of obstruction be caused. Local Authorities did not always like to run to the expense of glazed bricks, and private individuals were not always liberal. In the model by-laws issued by the Local Government Board there were several illustrations of air inlets which were useful. He explained the methods he had adopted in certain cases and criticised some of the diagrams illustrating the lecture. The most frequent trap to stop up was the one under the sink. Servants were not supposed to have any education, so the householder must look after these things himself. If therefore servants would stop up these traps, then let them take the traps away and connect them over the head of a gully in the ordinary way. The familiar little copper flap acted far better than any trap could do. With regard to the lavatory basin shown in Fig. 21, this, he thought, was a toy arrangement, and expensive. The simpler an apparatus could be made the better. The proposed water regulations provided for the overflow being carried right through the wall, and this certainly did away with the objection of the pipes choking up, for they would then act in the nature of warning pipes. He thanked the author of the paper for the treat he had given them in putting his thoughts together in the form of a paper. Engineers were often apt to look at matters in a superficial manner, and did not always collect their thoughts as Mr. Jensen had collected his. That was one reason why they should all join in thanking Mr. Jensen for putting the matter before them so clearly.

Mr. Clifford Smith said the paper was a valuable contribution to improvement in sanitation, and he hoped this would not be the last paper Mr. Jensen would write on the subject. He was surprised, however, to find that he had left out the important matter of bath wastes, which were often so much more objectionable than basin wastes. With regard to the remark of the last speaker as to there being a little faddism in sanitary matters, he would join issue on that. He thought if they were still more faddy they would be a great deal more healthy. If there was one thing more than another which is thoroughly neglected in London and the country it is the sanitary well-being of houses. Nobody made a study of it except, perhaps, those who gained their livelihood by it. The consequence was that if anything went wrong, it was generally put down to the fact that the drains were wrong again, or the sink always smells and nobody bothers about it. If it were understood that it is possible to rectify defects and that the drains needed as much attention as a sick person, his opinion was that they would be much healthier. Anyone who had had anything to do with ventilation and drainage pipes must have had the disadvantages of rust brought to his notice. Lead pipes would hardly do where they were subject to rough usage—in a school, for instance, where every boy had to kick the pipe well every day. He found it was advantageous to have glass-enamelled iron pipes; these would do all that was wanted. The suggestion to increase the size of the ventilation pipes at the bend was an excellent idea, but the enlargements would have to taper off, as it would not do to suddenly increase the diameter, as this would create an interruption of the air passage of the whole pipe. The syphonage case of the closet mentioned by the lecturer was a remarkable thing. As to the school, he did not think the trouble there was at an end, and it was to be hoped when Mr. Jensen was called in again his advice would be accepted. There was something radically wrong in that establishment. The indiscriminate distribution of ventilating pipes was altogether wrong. A man who designed a system and distributed his pipes so carelessly would be also likely to fail in the primary object of his whole drainage system. He remembered an instance in which there was an outbreak of tonsilitis very regularly, and at last the cause of the trouble was found to be due to foul air being driven down from the ventilation pipes of drains, the pipes being on the roof of a neighbouring house, and affecting the bedrooms. The occupants of these rooms were always affected. He thought that that instance bore out what Mr. Jensen had referred to. As to the question raised by Dr. Shirley Murphy, he had taken out many earthenware pipes, and in no case had he found the material had degenerated. Where they were broken the fault was entirely due to their being laid on clay. The dry summers we had had would dry up the clay to a considerable depth, the pipes would settle and then crack. Except under these conditions he was of opinion the earthenware pipes would do all that was expected of them, and would be found intact if overhauled at the end of thirty years' time. But country-made pipes, more particularly those laid in soft clay, when brought to the surface at the end of fifteen years or less would break away and crumble, but if exposed to the air for a few weeks would soon harden.

Dr. Farrar complained that there was no precise formula as to the fixing of ventilation pipes. Many he knew were brought out at right angles, rendering them quite negative in results. He ventured to suggest that ventilation pipes should always be passed up straight through the eaves, and the rain pipes brought round in bends, rather than the ventilation pipes diverted, as is often now the case.

Mr. Max Clark said that no one could hear the author's paper without feeling that Mr. Jensen had devoted a very considerable amount of attention to simple details, and he (the speaker) had always found that this really constituted good sanitation. The case mentioned by Dr. Shirley Murphy pointed to the desirability of examination of drains after they had been laid for some years. He did not agree with the writer of the paper on the question of lead ventilation pipes, because when steam or hot water was discharged into the soil-pipes lead ventilation pipes became the worst thing that could be had. With regard to anti-syphonage, the County Council by-laws were quite clear in their regulations as

to where the pipes should be connected with the trap. There was one other thing essential to good drainage, and it was as essential as good workmanship, viz., to keep the fittings and apparatus of all kinds as few and as simple as possible. Each apparatus which could be omitted is so much to the good. One of the gullies in the yard (Figs. 12 and 13), he ventured to suggest, was unnecessary.

A vote of thanks having been heartily accorded to the author, Mr. Jensen rose to return thanks and to reply to the discussion.

Mr. JENSEN said that the President in his criticisms had remarked that drainage work should be so designed that it should not make any allowance for scamping. Perhaps he (Mr. Jensen), in alluding to scamping, had hardly conveyed what he intended. He meant that the design should be in all cases so good that, if scamping did take place and remained undiscovered, the evil results would be minimised. It was far from him to wish to encourage scamping. As for air inlets, he had not mentioned them, as the subject had been already touched upon in a previous paper by Mr. Lawford. The point had been fully discussed on that occasion, and, as there was nothing new to record, any allusion made to the subject would have been in the nature of repetition. Dr. Shirley Murphy had mentioned the case of certain drains which had sunk and cracked, and some discussion had arisen upon the point. Of course, the sinking of drains was not at all unusual, but it almost invariably happened through faulty materials or workmanship, or owing to natural subsidence of the soil. In some cases drains were found to go very soon after they were laid, and in others they would last for a great many years. Upon unsuitable soil the difficulty would not be overcome by laying drains on a concrete bed. He had recently had a case at Wimbledon where the drains had been laid on and surrounded by concrete only some two or three years ago, yet the drains had cracked through the settlement of the ground. Both the concrete and the drains had given way. He thought that the remedy lay rather in the use of iron pipes of great strength laid upon a very broad and thick bed of concrete. Other precautions might suggest themselves when the nature of the ground was known. Mr. Silcox had recommended enamelled iron pipes in place of lead pipes for ventilation. His own experience was that the enamel was liable to crack, and that the pipes rusted behind the enamel and caused it to come off. He should say that such cracking would be very liable to occur where that drainage received steam or hot water, as mentioned by Mr. Max Clark. In such cases one might have pieces of enamel to contend with as well as rust in ventilation pipes. Lead pipes were certainly liable to injury by kicks, &c., but they could be protected by fixing sheet-iron guards round the portion liable to be damaged. Mr. Silcox had said that he preferred to leave drains without any air inlet at all, if he could not place the inlet in a position in which it would be absolutely safe. He presumed that he meant in cases where the drains had more than one outlet, and in which one of the outlets might occasionally act as a ventilating inlet. If there was but one outlet and no inlet, there could be no ventilation whatever, as two openings at the least were necessary for this. As to the alternative of having the air inlet at the same level as the outlet — at the top of the roof — that would in most cases result in stagnation altogether, as the heavier gases would collect at the bottom of the drain and virtually form an air trap. Mr. Angel thought that the evils of an open space at each joint caused by the disappearance of the gasket would not be serious. He (Mr. Jensen) took a more serious view of the matter, more especially in the case of stoneware drains with their numerous joints. The gases generated would alone be a serious objection, to say the least. The edge of the spigot did not always fit closely against the bottom of the socket, as had been stated by Mr. Angel. Very frequently the two were so rough, and touched so badly, that there might be an open space of as much as a quarter of an inch or more between them. Mr. Angel, in referring to the lavatory shown in Fig. 21, thought that many people would object to it on account of its cost. As a matter of fact that particular lavatory was as cheap as the majority on the market. It had been specially made so, he understood, in order to compete with them. Referring to Mr. Clifford Smith's remarks, he (Mr. Jensen) admitted that he had not specially mentioned baths. They were much the same kind of fitting as lavatories, and did not differ from them as regards the treatment of their wastes. What applied to one applied mostly to the other. With regard to the case of syphonage mentioned by him, he thought that this could have been due to no other factor than the two currents of air which were pulling against one another in the soil-pipe. That was the only explanation that he could find at the time after carrying out various experiments. Dr. Farrar had mentioned the case of a ventilation pipe with four right angles and running round the eaves. Of course that was one of the things that should be avoided. Probably the angles would reduce the force of the current to extremely small proportions, and that was one reason why he (Mr. Jensen) had advocated an increase in the sectional area of the ventilation pipe where there was an unavoidable bend. In the particular case instanced by Dr. Farrar the bends could no doubt have been avoided. Mr. Max Clark had desired some particulars regarding slip joints. He (Mr. Jensen) had made a rough sketch of one such joint. A socket was formed on the lower pipe, and the lower end of the pipe immediately over it was pushed into it, and the joint between the two made by a vulcanised india-rubber ring. In that way some room was given for the upper pipe to expand into the socket on the lower pipe.

Mr. MAX CLARK said that he asked the question because it was found that the india-rubber rings deteriorated.

Mr. JENSEN agreed that that was the case, and that the rings required renewal occasionally.

The meeting then terminated with a vote of thanks to the chairman.

CORRESPONDENCE.

(*To the Editor of* THE SANITARY RECORD.)

(*We do not in any way hold ourselves responsible for opinions expressed by our correspondents.*)

"A GOOD RECORD."

SIR,—" Observer's " notes on the township of Batley, I am afraid, are likely to mislead some of your readers. I thought on reading the same that Batley must be a health resort, but when I came to look into the matter more thoroughly, what did I find? Why, that the death-rate of persons dying from infectious diseases for the past five years has been as high in this town as that of the majority of the towns and cities in the West Riding. This is the fairest criterion of the health of a town, not picking a few good examples of freedom from certain ailments, when others more dangerous and more prevalent are passed over. What about typhoid in Batley since 1895!—Yours faithfully,

March 16th. ANOTHER OBSERVER.

A PETITION in opposition to the Prestatyn Urban District Council's Water Bill to secure the existing waterworks, &c., has been filed on behalf of Mrs. Laura Elizabeth McLaren, the wife of Mr. Charles McLaren M.P.

Sanitary Inspectors' Associations.

LONDON.

The Venerable the Archdeacon of London presided over the eighteenth annual dinner of the Sanitary Inspectors' Association held with much success on Friday last at the Holborn Restaurant. Among the company were Alderman Dickinson, J.P., L.C.C., the Master of the Carpenters' Company, the Mayors of Finsbury, St. Pancras, Deptford, Greenwich, and Poplar, Dr. Haward, Dr. F. J. Allan, Dr. Gay, Alderman Redfern, Dr. J. Groves, Rev. C. N. Whitfield, Mr. E. Lewis Thomas, B.A., Mr. A. Richardson, Mr. C. Gordon, Councillor Wilson, Mr. H. Lovegrove, Mr. W. H. Grigg (chairman of the Council), Mr. T. G. Dee (treasurer), Mr. T. Ashdown, Mr. I. Young, Mr. E. Tidman, C.E. (hon. secretary), and over a hundred members of the Association. Pressure of parliamentary duties prevented the attendance of Sir Walter Foster, M.P., Col. S. A. Sadler, M.P., and several other gentlemen, the unavoidable postponement of the gathering on two occasions having led to the absence of many prominent gentlemen who had originally accepted invitations. A capital musical programme was performed under the direction of Mr. T. F. Strutt, the Minnesingers quartet being the principal artistes.

The toast of "The King" was proposed in appropriate terms by the Chairman and enthusiastically drunk, the National Anthem being sung.

The Mayor of St. Pancras proposed "The Houses of Parliament" in a humorous speech, and this was acknowledged by Alderman Redfern of Stockport.

The Mayor of Finsbury submitted the toast of "The Defenders of the Empire," for whom Dr. Groves, Medical Officer of Health for the Isle of Wight, responded, giving his experiences as Medical Officer to a station hospital. He recounted an amusing instance of War-office red-tape, he being consulted by the military authorities as to whether the Local Sanitary Inspector should be allowed to inspect the hospital where typhoid fever had broken out. Of course, he gave his consent, and it was found that the military authorities were pumping water from a polluted well at a cost of 7s. 6d. per 1000 gallons in order to save paying the Borough Corporation a shilling per 1000 gallons for the purest possible water from the chalk.

Dr. Haward, who had been through the Crimean war, also briefly replied to the toast.

Dr. Groves proposed the toast of "Local Government." He said the importance of local government in this country was to be gauged from the fact that it had in its care the chief asset of the State, viz., the health of the community. Local government had to protect the people from what he would call the tyranny of financial interest and the operations of monopolists. Public health was not merely a matter of microbes and preventable disease, but was related to happiness and education. Acts of Parliament were all very well, but they also needed to teach the individual how to preserve his own health and the health of those dependent upon him. The environment of the individual had so much to do with health that the beautifying of our cities was and ought to be a matter of concern to those who regulated our complex civilisation. Those who were connected with local government in this country he believed were doing their level best to bring about a good state of things, and Medical Officers and Sanitary Inspectors were alive to the need for vigilance and zeal. He did not think they would be found wanting, but he referred in strong terms to the uncertain tenure which many Health Officers worked under in the rural districts, and contended that this was a matter which ought to receive parliamentary attention. He was glad to think that in the matter of superannuation and tenure of office the Medical Officers and Sanitary Inspectors were now working heartily together, and justified this on the ground that they had interests in common. (Applause.)

Mr. Ald. Dickinson, J.P., late Chairman of the London County Council, who was loudly cheered, responded to the toast. He said local government was somewhat like a locomotive engine, and depended on three principal factors—the machinery, the guiding hand of the driver, and the motive force. In this country the machinery of local government was a large band of able, honest, and skilled experts, the value of whose services the local governing bodies were only too willing to recognise. He believed that the expert officers were more the personification of local government to the masses of the people than any others connected with local government. Most people knew what an Inspector was, but a councillor or alderman was largely name only. He realised that the expert assistance given to local government had vastly improved to what it was even a few years ago. Now it was laid down that a Medical Officer or Sanitary Inspector should be a man who had made a study of his profession, and very trying and noble was the profession of Sanitary Inspector. The guiding hand of local government was, of course, the governing authority; and here, again, especially in London, there had been a process of great improvement. He recounted some amusing experiences of his own twenty years ago in vestrydom, and said that the old position in which men who ought never to have been entrusted with local government was, he believed, responsible for much of the overcrowding evil of to-day. Had the authorities years ago done their duty when it was comparatively easy to have done it, the serious congestion of population would not now be experienced. There was the third division of local government, the motive force, viz., public interest and concern in their representative bodies. The reason why in the past local government was of a feeble and inefficient kind was because no one took any interest in their election or their administration, so that persons whose interests conflicted with the public interest easily got returned. This had to a certain extent improved, but he believed that the public in this respect had shown far less improvement than either the experts or the governing bodies themselves. For instance, at the recent London borough elections only one-third of the voters went to the polls, and at the last County Council elections only a-half of those entitled to do so recorded their votes. So long as the public showed indifference in this way, so long would it be impossible to get good administration. Good administration depended upon two things, upon the intelligent interest of the public in the proceedings of those bodies, and upon the purifying influence of a continual stream of sunlight being thrown upon the actions of those bodies by the Press. (Applause).

Mr. Alderman Redfern and Mr. Councillor Wilson also responded to the toast.

The Chairman then gave the toast of the evening, "The Sanitary Inspectors' Association," and described in detail the constitution, objects and work of the organisation, which he said had justified its existence by all that it had achieved during the past eighteen years. He regarded such an organisation as theirs as being essential to the improvement and success of the profession. To young Inspectors especially the Association was of great use, for many of them on entering upon their duties found themselves faced with all sorts of difficulties, owing to vested interests, stupidity and prejudice. To such Inspectors it was a great help and encouragement to know that he was backed by an influential body of his colleagues. He warmly recognised the great public work done by Sanitary Inspectors, who regardless of their own safety, fought dirt and disease wherever it was found. He wished it was the duty of

the Inspector to see to the ventilation of churches, for he had to admit, from what he knew in his official capacity, that the proper ventilation of churches was sadly neglected. He was delighted to have had an opportunity of expressing his appreciation of the labours of members of their profession, and urged them to continue their efforts for the public good, despite all drawbacks and discouragements. (Applause.)

The Chairman presented the following awards by the Association at the Health Exhibition held at Lincoln in connection with the Provincial Conference of the Association in 1899, viz.:—Silver medal, Oates and Green, of Halifax, general excellence of manufacture; bronze medal, Guest and Chrimes, general excellence of exhibit; certificates, Wilson and Stockall, ambulance appliances; Charles Duckering, general excellence of exhibit; Arnold and Co., Limited, distilled waters; E. F. Arnold, R.P.C., exhibit of plumbing defects; and Lockerbie and Wilkinson, general excellence.

Mr. W. H. Grigg, Chairman of the Council, responded to the toast, and thanked the Venerable Chairman and Mr. Dickinson for their kindly remarks. He referred to the action taken by the Association on behalf of Sanitary Inspectors generally in regard to libels which had been placed upon them, and pointed out that by the success of the action corporate bodies of professional men had been benefited, for it was now established that honourable professions could not be libelled in general terms with impunity. He also referred to the co-operation of the Medical Officers' organisation and their own in supporting the Bill for superannuation and tenure of office promoted by the British Medical Council, and said the Sanitary Inspectors had been splendidly met by the Medical Officers. He was convinced they would not be deserted, and as a consequence of the agreement arrived at, was about to propose that their own Bill should be abandoned. (Cheers.)

Mr. H. Lovegrove proposed the toast of "The Chairman," and this was drunk with musical honours, the Ven. the Archdeacon of London suitably replying. "The Visitors" was proposed by Mr. W. W. West, and responded to by the Mayor of Deptford; and the toast of "The Press," submitted by Mr. Aubrey Richardson, hon. solicitor to the Association, was acknowledged by Mr. C. E. Ady, of The Sanitary Record.

SANITARY PRACTICE IN REGARD TO LEVELLING HOUSES.

The first of the Freeland course of popular lectures was recently delivered in the Glasgow and West of Scotland Technical College by Mr. Gilbert Thomson, M.A., C.E., who dealt with "Sanitary Practice with Regard to Dwellings: Past, Present, and Future."

The reference to the past was limited to the period of which the lecturer had personal experience—fully twenty years, covering the time during which most of the modern developments had taken place. Illustrations were given of some of the glaring faults in design and construction, and of the curious attempts at improvement that were then frequently encountered, and from these the course of real improvement was traced to its present stage of development. While the past, with regard to sanitary practice, might be fairly described as the time when each one did what was right in his own eyes, the present was, on the contrary, a period of very rigid sanitary supervision, with the result that we now had a very much higher standard of construction, and that a number of general principles were fairly established. We were entitled to congratulate ourselves on that improvement, but we were not to imagine that we had reached perfection. For example, one improvement had gradually been piled on the top of another, and we had, to some extent, incongruous and unnecessary demands made by sanitarians. Not to speak of the excessive ugliness of some of the so-called sanitary work, which made an eyesore to whole neighbourhoods, there was a distinct tendency to elaboration which was not only needlessly costly, but actually less satisfactory than simpler and cheaper methods would be. The various methods of testing by smoke, air pressure, and water were experimentally illustrated, and the opinion expressed that the smoke test ought to be entirely abandoned as a standard on account of its uncertainty. It was most useful for exploring work, but entirely unfit to give proof of soundness. The water test and the air test could give that proof, but while the water was of limited application and involved several practical difficulties, the air test was of easy application, gave a certain result, and met all the requirements of a standard test. The drainage of the new Alexandra Infirmary at Paisley was shown as an illustration of a system that could be at any time, and with ease, tested in this absolute fashion. With regard to the future, the lecturer expressed the hope that those in authority would devote their attention to two points—the enforcement of the highest possible standard of construction, and the removal of every complication that was not absolutely necessary. In that way it might be hoped that the Sanitary Inspector might so improve public opinion and raise the universal practice as to make the compulsory part of his own duties needless.

The lecture was illustrated by lantern slides and experiments.

THE CLEANSING OF CISTERNS.

This important subject is referred to by the Medical Officer of Health for the urban sanitary district of Wimbledon in his annual report. He says:—"The investigation in connection with cases of infectious disease has revealed, in many instances, the improper positions in which the drinking water cisterns are placed. They were found in every conceivable position, often almost inaccessible, and generally uncovered, in coal cellars, water-closets, and under bedroom floors, in the latter cases the ill-fitting boards of the floor forming the cover. This increases the difficulty of the occupier to cleanse the cistern if he should so desire, but unfortunately, this precaution is often neglected. Cisterns have been found to become the last resting place of mice, birds, &c., and these decomposing, cannot possibly benefit the persons using the water. The best remedy for these evil conditions would be for every house to be provided with a draw-off tap direct from the rising main for drinking purposes. This cannot be done, as the water companies supplying the district do not give a constant service. New regulations deposited by them with the Board of Trade for approval, however, require that 'every cistern used in connection with the water supplied by the company shall be made, and at all times maintained water-tight, and be properly covered with a close fitting lid, and placed in such a position that it may be readily inspected and cleansed.' If approved, this regulation should prevent in the future the evil conditions mentioned above."

A Local Government Board inquiry was held last week at Folkestone with reference to the application of the Corporation for powers to construct an electric tramway system within the borough. There is a great divergence of opinion over the matter, the residents in the fashionable quarter contending that tramways will spoil the unique beauty of the town.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

THERE was an excellent muster of members at the meeting of the Municipal and County Engineers' Association at Wimbledon on Saturday last; the programme was admirably arranged and carried out; the day was marked by an absence of rain, and when the proceedings were completed the thanks which were accorded to the indefatigable and popular hon. district secretary—Mr. R. J. Thomas—and to the untiring Engineer of the Wimbledon Council—Mr. C. H. Cooper—were as hearty and sincere as they were loudly acclaimed.

THERE was but one opinion held, it was evident, as to the desirability of Local Authorities throughout the kingdom being urged by an official circular from the Association to send their Surveyors to the Engineering Congress to be held in September next in Glasgow, and to pay their expenses. Local Authorities benefit equally as much as, and probably more than, their officials from the latter attending such congresses and exhibitions. Their Surveyor is brought into contact with his professional brethren and his knowledge is kept up to date on the various matters which lie within his province. He attends the reading of papers, takes part in discussions, inspects municipal works in progress from which he gains new ideas, which are subsequently utilised for the benefit of the Local Authorities, and the knowledge gained is diffused, and administration and localities benefitted. The resolution to send out a circular on the subject to each Local Authority in the kingdom was carried unanimously.

MR. COOPER had an interesting record to chronicle of work carried out since the previous meeting of the Association held two years ago in Wimbledon, which he described with his usual modesty, and after he had concluded his description, there was, as is customary and pleasant, a considerable string of questions from members to elucidate information. Some of these questions were, it must be said, of a curious order; for instance, one member wanted to know why in the provision of underground sanitary conveniences more water-closets had been made for females than males, and another member invited the reply which Mr. Cooper wove in with a quaint story as to his reason for providing portable baths in artisans' dwellings.

THE burning topic of the housing of the working classes was of course in evidence, one of the ex-presidents—Mr. Harpur, of Cardiff—emphasising the current opinion that Local Authorities are unable to compete with private speculators in the provision of such dwellings, owing to the restriction of the Local Government Board, that loans for such dwellings should not be granted for a longer period than thirty years. This restriction, which is so absurd, is held to be a striking commentary as to the apathy of the Local Government Board on the subject. If there were any desire on the part of this Government department to assist Local Authorities in grappling with this problem the loan period would be extended, but living up to its reputation as an obstructive, and not an auxiliary department, the nation must suffer until many years have passed wherein the Board may be educated.

I IMAGINE there are few towns of its size which can boast of such an excellent suite of stables and store and stock-rooms as Wimbledon. The exterior elevation of the stables, which are situated in a residential road, is highly ornate, and between the building line and the road the land has been laid out as a small public garden with seats, &c. Surveyors who want to know of an admirable method of book-keeping for stock accounts and of time-keeping may be advised to copy the system initiated by Mr. Cooper, which is an admirable one.

THE infectious hospital constructed from the designs and under the superintendence of Mr. Cooper contains all the most modern appliances and improvements. The idea of conveying steam from the sewage pumping station in iron pipes for some 730 yards to the disinfector is an unusual one, and has been carried out so as to dispense with the necessity for a steam boiler at the hospital.

AFTER luncheon was partaken of at the Baths, Worple-road, brakes were entered for a drive to the Streatham destructor, Ilston-road, Tooting, which was erected by Messrs. Beaman and Deas, for the Streatham Vestry, now incorporated in the borough of Wandsworth. The automatic feeding arrangement introduced by Mr. H. J. Martin, the Surveyor to the late Vestry, and now Surveyor under the Corporation, was explained by Mr. Martin and seen in work. Subsequently the party drove to the combined electricity and refuse destructor works of the borough of Fulham. The scheme has been well developed on broad and progressive lines, but we were unable to ascertain whether the combined system is a success. The destructor, I am bound to notice, was not seen at its best, and improvements are much needed to reduce the excessive amount of dust and fumes in the building. Mention may also be made here of the fact that the combined electricity and destructor works at Wimbledon, constructed from the designs of a consulting electrical engineer, have not, so far, proved successful, and the destructor plant has had to be put out of use.

I UNDERSTAND that the forthcoming summer session of the Municipal Engineers' Association is likely to be an interesting one, owing to the numerous meetings at various places which are in prospect. Amongst other towns to be visited, and already arranged for, are Chichester, Lowestoft, Oswestry, and West Bromwich, whilst the annual meeting will be held at Leicester—a fixture which foreshadows the election of Mr. E. George Mawbey, the Borough Engineer of that town, to the president's chair. SENEX.

BOOK RECEIVED.—"How to Become a Municipal Engineer." J. Freebairn Stow. 1s. net. St. Bride's Press, Limited.

BOILING-POINT OF WATER.—Most persons are apt to regard the point at which water in the domestic saucepan boils as a fixed quantity, unalterable as the laws of the Medes and Persians; but the cooks of a certain town in New Mexico have discovered that, in consequence of its great altitude above the sea, water boils there at 202 deg. Fah. instead of at the normal 212 deg. This means that all the cooking calculations depending upon the heat of the water have to be revised. Everything from a breakfast egg to a silver side of beef takes longer to cook than it does lower down in the atmosphere. Another thing which militates against the calculations of the ordinary cook of the same town is that the air is so dry that vegetables are deprived of half their natural moisture, and must be left a long time in water to recover themselves before being cooked. In connection with this matter of the boiling-point we might observe that if our cooks at home could only realise the fact that it is impossible to heat the water in an open vessel above boiling-point, they would save much of the gas used in so many houses for fuel.—*Chambers' Journal.*

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

The Sanitary Record

AND

Journal of Sanitary and Municipal Engineering.

MARCH 21, 1901.

THE SANITARY NEEDS OF WEST AFRICA.

FEW of us probably have devoted much thought to the question of sanitation in West Africa, for the simple reason that it does not come under our immediate cognisance. But to judge from the statements made by the deputation from the Chambers of Commerce of Manchester, Liverpool, and London, that waited on Mr. Chamberlain last Friday, the question is a very serious one, and in view of the increasing intimacy of our commercial relations with the Gold Coast, it possesses a most important practical interest. Numbers of our young men are sent out there every year as representatives of trading firms at home, but at present it requires no ordinary inducements to persuade them to risk their health in that insalubrious climate. The climate of the Gold Coast has long possessed an unenviable notoriety. It is *par excellence* the "uninhabitable house" of the British Colonies. And we now learn that it is not only the climate—for which nature is responsible—that is to blame for the fearful unhealthiness of the district, but that absence of sanitation—for which the responsibility is human—is in large measure a contributory cause. In Lagos, for instance, the methods of sewage treatment could hardly be more crude or primitive. The sewage is simply turned into the lagoon, to foster and breed disease. The water supply, too, is of the foulest character. The deputation stated that the Liverpool School of Tropical Medicine had done much in connection with the question, but their efforts would not be really effective until the Government took the matter in hand. The points to which they specially directed attention were:—(1) The removal and disposal of refuse; (2) complete surface drainage of the soil, and removal of bush and undergrowth; (3) removal of native huts, where their presence is a menace to the health of Europeans; and (4) the institution of sanitary regulations for observance by the public.

Mr. Chamberlain in his reply was most sympathetic, as, indeed, he always is with all movements calculated to improve the conditions of residence of our sons abroad. To make our West African possessions more habitable for colonists has long claimed his special interest. He was able to assure the deputation not only that the Governors of the Gold Coast had been urged to spare no expense to make West Africa more habitable and healthy, but also that many of the schemes suggested were already in preparation, especially with regard to the disposal of sewage, the residences of Europeans and natives, the water question, and other matters. He accepted the suggestion of the deputation that a Sanitary Commission might be appointed to deal with the whole question, his proposal being that the London, Manchester, and Liverpool Chambers of Commerce should each appoint a member, with, perhaps, someone from the Colonial-office as secretary, and that these representatives of the Chambers should appoint a scientific expert to assist them, whose suggestions they should weigh as men of business. For the ultimate responsibility of deciding what must be done could not be left to any scientific expert. The question of cost must be determined, and they would have to consider the question in that light. The question of how the necessary funds could be provided would have to be referred to the Commission. The Manchester Chamber had expressed itself as willing that a sanitation tax should be imposed, but they suggested that economy rather than taxation should be the means of raising the money required. These would be points that would be left to the determination of the Commissioners. The scheme as outlined by Mr. Chamberlain is eminently businesslike and practical, and we trust to see it ere long in opera-

tion. It should be productive of the very best results.

Plague at the Cape.

The telegraphic reports of the hold that the plague is getting in Cape Town during the last few weeks show that the situation is acute. Originally introduced through the agency of rats, it first established a firm footing in the native quarters, especially in the vicinity of the docks, but it subsequently spread to the European population, and the latest reports indicate that the proportion of European cases is increasing. There have been over a hundred cases, and something like forty deaths have occurred. In consequence of the gravity of the outbreak, the Corporation have entrusted the Government with the full control of the sanitary arrangements of the city. Among the measures that have been adopted are the appointment of a special Plague Advisory Board, including Dr. Gregory, the Government Health Officer; Dr. Fuller, the City Health Officer; and Professor Simpson, the bubonic expert; the systematic cleansing of all houses, for which purpose the city has been divided into districts, each in charge of a doctor, assisted by a sanitary staff, and with the aid of scavengers to destroy the rats; and the removal of the natives from the affected quarters to a special location outside the city, the hovels from which they are removed being either cleansed or destroyed. As usual in such cases, the native population are a source of much trouble. Their dwellings are thoroughly insanitary, and they conceal cases of plague. But they appear to be submitting on the whole to the preventive measures, for wholesale inoculation is proceeding, 2000 having been inoculated in one day. In addition to the Kaffir native population, however, there is a considerable Malay element, who are less tractable, on account, it is said, of their religious views. The removal of one of these people, who was suffering from the disease, was only effected in the face of considerable opposition, but on an attempt being made to remove the "contacts," the Malays assembled in considerable force and drove off the police and municipal officers, and they have resolved in mass meeting to resist eviction to the locations, like the Kaffirs, by force if necessary. The Malay priests, to their credit, are lending their support to the authorities.

The Small-pox Epidemic in Glasgow.

Dr. Chalmers' weekly bulletin last Friday, in connection with the epidemic of small-pox in Glasgow recorded 103 admissions during the week, 122 dismissals, and 23 deaths, leaving 404 cases in hospital, as compared with 446 for the preceding Friday. The total number of cases treated in hospital since the commencement of the outbreak was 1449, with 178 deaths. Too much praise cannot be given to Lord Provost Chisholm and the Sanitary Department for the untiring energy with which they are working. The work of re-vaccination is steadily proceeding so as to embrace as far as possible the whole city. On the invitation of the Lord Provost, a conference of Glasgow doctors was held last week in the City Chambers, under the presidency of the Lord Provost, about 200 doctors being present. The Lord Provost explained that the task they had to undertake was to meet face to face the people who were indifferent to vaccination, who represented the *vis inertiæ*, the strongest power on earth, the most difficult to move. The proposal was to cover the city by direct and personal appeals, and they desired the medical men to assist them. The city had been mapped out into 1100 enumerators' districts in connection with the coming census, and it was proposed to make use of these. He urged that there need be no delicacy on the part of practitioners who went into the service of the Corporation in the discharge of their duty. The object was to have every house visited. With these systematic measures the Authorities expect that the disease will soon be throttled.

A Magnificent Gift.

No other description is expressive of the action made public at the beginning of this week to the effect that the Cadburys have made over to a Trust their model estate at Bournville for the benefit of their workpeople. The terms of the gift are so clear that no misconception can ever arise as to the meaning and intention of the donors, and we cannot but rejoice in the prospect of a multiplication of cottage colonies in which true home-life may be enjoyed by those who dwell in them. It is estimated that the value of the property made over to the Trust is between £170,000 and £180,000. The estate consists of about 416 acres, with 439 cottages erected upon it. Mr. George Cadbury has given to the Trust 330 acres, of which about one-third has been laid out. Upon this portion of the estate 370 cottages have been built, and of these 143 have been sold at cost price on leases for 999 years, 3 per cent. being charged to those who paid less than half of the cost, and $2\frac{1}{2}$ per cent. to those who paid at least half the cost. The remaining 227 cottages and shops are let to weekly tenants, and the rents of these, ground rents, &c., are paid into the Trust. There are about 200 allotments, which are in much demand from the inhabitants of the adjacent manufacturing villages. There are two gardening classes for about thirty youths, each of whom has a small plot to cultivate; these classes are under the care of the Worcestershire County Council. The total rent roll, exclusive of repayment for cottages sold, is £5246 a year, which, after current expenses are paid, is devoted to the development of the estate, and the building of more cottages. The estate is close to two manufacturing villages, and a direct railway line from Birmingham bounds one side. When this estate is completed it is intended, with the income from it, to purchase similar estates, but the intention of the founder is that such estates may be developed as manufacturing centres, one-fifteenth only to be used for manufactories, one-tenth at least to be used for open spaces, and the remainder, as on the Bourn-

ville Estate, to be laid out for cottages and gardens, the buildings not to cover more than one-fourth of the land on which they are erected.

Progress in Italy.

The recent action of the leading authority on public health matters in Italy should have an excellent effect upon the national life of that country. The Higher Council of Health has sent forth a circular to all the subordinate authorities calling attention to the unsatisfactory conditions prevailing in some parts, and proceeds to point out how a change may be made. In the first place, the Council, esteeming that the mortality arising from cases of typhoid fever is relatively high, especially in the smaller communes—a proof that the hygienic conditions are unsatisfactory, and that the supply of drinking water is deficient—urges that the Act empowering the raising of loans for purposes of hygiene should be put into force with all possible despatch in the smaller communes. Then, with a view to the more effective prevention of tuberculosis, the Council urges the promotion of hygienic reform in hospitals by rendering obligatory the isolation of patients suffering from that disease, and the adoption of all precautions necessary to prevent its diffusion. The Council also recommends an inquiry into the state of the prisons, and the utmost extension of sanatoria by enlisting the co-operation of railway companies and great industrial associations. And, finally, the Council urges upon the army and navy authorities the importance of exercising the utmost vigilance in guarding against the admission of recruits suffering from tuberculosis

---

Tin-platers and their Work.

An important conference was held last week at Swansea between the Factory Inspectors and tin-plate makers of the district. The object of the meeting was to devise, if possible, better conditions for carrying on this important industry. The basis of the conference was found in certain suggested improvements in the arrangement and ventilating of tin-houses, so as to minimise any poisonous effects to workers from flux, bran-dust, &c., used in the manufacture of tin-plates. The Inspectors present were Messrs. J. A. Redgrave, E. H. Osborne (engineering expert), Dr. T. M. Legge (Medical Expert), Mr. Augustus Lewis, and Miss Rose Squire, whilst the Committee of tin-plate manufacturers was headed by Mr. Trubshaw, president of the Swansea Tin-plate Manufacturers' Association. The conference lasted all the afternoon. A report, it will be remembered, was made on the subject by Dr. Legge last year, in which he suggested that any injurious effects of zinc chloride, flux, and bran-dust, could be overcome by better ventilating arrangements, better draught, and shorter hours of labour at dipping plates, &c. These and kindred suggestions were discussed at length, and although no definite arrangements were come to, it was stated by Mr. Trubshaw that the conference had been valuable in removing a good deal of the friction and difficulties which had existed on the subject between makers and the Government Department. We think that other trades might well follow this example. The "round table" is a wonderful curative of friction and misconceptions of all kinds.

Municipal Engineers at Wimbledon.

On Saturday last the Municipal Engineers made Wimbledon their rendezvous, and a most enjoyable meeting resulted. Perhaps no suburb has made such gigantic strides of recent years as Wimbledon, and the Local Authorities have kept pace with the increasing demands upon them in a way that is eminently praiseworthy. The department of the Surveyor has been especially alive to the responsibilities, and the town is fortunate in possessing in Mr. Cooper an official who is fully capable of carrying out the important work which falls to his share. Few towns enjoy a better equipment, and in many respects the works are a model which might be followed with advantage in many places possessing greater pretensions to importance. The visitors on Saturday appeared to be duly appreciative of this, and inspected the various points of vantage which were open for their special benefit with more than usual interest. In explaining the details Mr. Cooper was indefatigable. The fever isolation hospital and splendidly-equipped offices of the Local Authority elicited praise on all hands, and the visitors left the town feeling that their visit had been something of a revelation. The party was subsequently driven to see the dust destructor at Streatham, and thence to the recently-installed electric lighting plant at Fulham.

PORT SANITARY AUTHORITIES AND THE PLAGUE.

Under the presidency of Dr. Fraser, Hull, a meeting of the Association of Port Sanitary Authorities was held last week in Liverpool.

Dr. M. K. Robinson, Dover, read a paper on "The Recognition of Plague," and said that both at Hull and Glasgow the cases showed that the aid of the bacteriologist was necessary to establish a proper diagnosis and clear up any doubt in the history of the disease. The plague had evidently established a foothold at the Cape, and sanitary authorities should put on their armour and fully equip themselves. That would mean expense, but the Local Government Board should be asked to provide a bacteriological department in connection with the study of this dangerous disease.

Dr. J. Wright Mason, Hull, read a paper on "Recent Experiences of Plague in Hull," describing the measures taken to check the disease, which was there confined to one vessel.

Dr. D. S. Davies, Bristol, discussed the necessity of special care in supervising the discharging of cargoes of vessels from infected or suspected ports.

Dr. Collingridge, London, emphasised the impossibility of diagnosing the plague without bacteriological examination.

Dr. Hope, Liverpool, urged the importance of an early recognition of the plague, and said that in Liverpool they had been fortunate in securing the services of

a gentleman thoroughly cognisant with the conditions associated with plague in India. Port Sanitary Authorities no longer groped in the dark, having now precise knowledge on the most essential points. It was not likely that the plague would develop in this country to a disastrous outbreak, but injury might be done to commerce, as perhaps the South American Republics or the North American Republic might impose a rigid quarantine. Vessels having plague rats on board should be treated as plague-infected ships.

A resolution was adopted that the Association, recognising the great danger associated with the discharge of vessels infested by rats, recommend the Local Government Board to alter the law so as to strengthen the hands of Port Sanitary Authorities in such matters.

INCORPORATED ASSOCIATION OF MUNICIPAL AND COUNTY ENGINEERS.

After an interval of several months having lapsed since the last meeting of the Association, the members met at Wimbledon chiefly on the invitation of Mr. C. H. Cooper, the Surveyor to the Council, and through the desire of the popular district secretary Mr. R. J. Thomas, C.E., Aylesbury. Few surveyors work more for the good of the Association than these two gentlemen, and their joint efforts resulted in a large attendance, and in the provision of an interesting programme of visits to municipal works in progress. The members met at the Council Chamber, Wimbledon, where a short meeting was held, presided over by the president, Mr. C. H. Lowe, of Hampstead. An interesting discussion followed on the introduction of a resolution, which was unanimously carried, that local authorities should be asked by circular letter to grant facilities where possible for payment of expenses to their Surveyors to attend the Glasgow Congress of Municipal Engineering, to be held in September.

Mr. Cooper subsequently described the municipal works in progress, and the chief points of interest attached to them, among which were the new road bridge over the London, Brighton, and South Coast Railway, the depôt and stables in Queen's-road, the latter of which has accommodation for thirty-nine horses, the isolation hospital recently constructed, which has accommodation for fifty patients. One of the interesting features in connection with it was that the steam used for disinfectors and numerous other purposes was brought in 3in. pipes from the pumping station at the farm, a distance of 2200ft., thus effecting an economy in dispensing with a boiler and attendant at the hospital. The reduction in pressure of the steam in transit, Mr. Cooper said, was only 5 lb. Plans of proposed new sewage settling tanks—the existing ones having a capacity equal to one-half day dry weather flow—were described, and a septic tank was intended to be also constructed. Plans of additions to electric light station, of a recreation ground, and of artisans' dwellings to let at 7s.6d.per week each, and of flood prevention works, were also described.

A short discussion followed Mr. Cooper's paper, and in reply to questions he stated that the cost of construction of the hospital was at the rate of £400 per bed. The artisans' cottages cost £270 each, and provision was made in them for portable baths. A vote of thanks to Mr. Cooper was heartily accorded. Subsequently the members proceeded to inspect the railway bridge, the depôt, stores, and stables in Queen's-road, and the isolation hospital in Gap-road. Luncheon was partaken of at the baths, Worple-road, after which they drove to the Streatham Destructor, Ilston-road, Tooting, and to the electric light station, Townsmere-road, Fulham.

National Health Society.

OFFICIAL TRANSACTIONS.

Examinations for the Diploma.—The result of the examinations on First Aid and Nursing for those ladies who are studying for the diploma of the Society, have proved most satisfactory, the examiners in both subjects expressing themselves much pleased with the high standard of efficiency attained by the candidates. The following ladies have passed in both the above-named subjects:—Miss Irene W. Cox, Miss Grace Looker, Miss Edith Olliff, Miss Lucy Spiller, Miss Georgina Bevan. These five ladies having previously passed the examination in Sanitation and Hygiene, have now only to satisfy the examiners in one more subject (Physiology) for the completion of the training for the diploma. Mrs. Carol Kelsey has also passed the Nursing and First Aid examinations, while the following ladies were examined and passed only in First Aid:—Mrs. Theodore Fisher, Miss Adeline E. T. Biggs, Miss Madeleine Stampa. Miss Julia Dupins and Miss Edith Gamble have both been successful in passing the examination on Nursing, and Miss Trevor Dickson in satisfying the examiner in this subject has completed her training for the diploma.

Examination for Drawing-room Certificates. — An examination on First Aid for the Society's drawing-room certificate has also been held at Berners-street. The successful candidates are:—The Hon. Dora Webster, Miss Eva Boord, Miss Cecil Buxton, Miss Frances Buxton, Miss Francis Crowle, Miss Hilda Dawson, Miss Dorothy Butt.

Elementary examinations.—We have also to report the result of the examinations in Nursing held in Yorkshire during the last week in February. Forty-one candidates presented themselves, and only six failed to reach the required standard. The examiner speaks well of the work done in each of the five villages visited.

The following summary may be of interest to our readers, as giving some idea of the lecturing and examining work done by the Society during the last three months. From it will be seen that over forty Homely Talks have been given in London to mothers' meetings, clubs, &c., during that time, and nearly 400 candidates have been examined in First Aid, Nursing, Health, &c., in various counties during the same period:—

County Council Work.—Lincolnshire, 7 weeks; Suffolk, 6 weeks; Sussex, 6 weeks; Bangor, 6 weeks; Hove, 6 lectures.

Homely Talks.—East Twickenham, 2 lectures. Chapter House, Mothers' Union, 3 lectures; Fulham, 3 lectures; Finchley, 1 lecture. Sutton, 2 lectures; Notting-hill, 1 lecture; Toynbee Hall, 2 lectures; Putney, 5 lectures; Lyndhurst-road Club, 6 lectures; George-row, 3 lectures; Henley-on-Thames, 1 lecture; Wantage Club, 9 lectures; Shoreditch, 1 lecture.

Berners-street.—First Aid, 6 lectures by J. Cantlie, M.A., M.B., F.R.C.S.; Nursing, 6 lectures by Sister Katharine; Public and Private Hygiene, 14 lectures by John Gay, M.R.C.S., L.R.C.P., D.Ph.; Chemistry, 8 lectures by E. J. Steegmann, M.B., D.Ph.

Schools.—Forest Hill, 6 lectures; Enfield High School, 1 lecture; Southbourne-on-Sea, 6 lectures.

Examinations.—Rye, 24 candidates, Nursing and First Aid; Blaenavon, 7 candidates, Nursing. *Lincolnshire:* W. Torrington, 11 candidates, Nursing; Hatton, 15 candidates Nursing; Alford, 15 candidates, First Aid; Brinkhill 16 candidates, First Aid; Chapel St. Leonards, 13 candidates, First Aid. Sawston (*Cambs*), 19 candidates, First Aid; Sibford Ferris, 22 candidates, First Aid. *Yorks:* Flamborough, 6 candidates, Nursing; Filey, 12 candidates, Nursing; Walkington, 6 candidates, Nursing; Dunnington, 7 candidates, Nursing; Hemingborough, 10 candidates, Nursing and First Aid. *Bedfordshire:* Harrold, 40 candidates, First Aid; Ravensden, 16 candidates, Nursing; Silsoe, 17 candidates, Health; Cranfield, 18 candidates, First Aid; Eggington, 18 candidates, First Aid. *Lincolnshire:* Burton, 22 candidates, First Aid; Conningham, 12 candidates, Health; Brocklesby, 23 candidates, First Aid; East Halton, 8 candidates, Nursing; Market Rasen,

19 candidates, Health. *Diploma:* 11 candidates, First Aid. *Diploma:* 9 candidates, Nursing. *Drawing-room:* 8 candidates, First Aid.

ASSOCIATION OF NATIONAL HEALTH WORKERS.

The monthly "At Home" for members of the Association will be held on Saturday, March 30th. Mrs. Norton has kindly promised to preside.

Public Works.

SEWERAGE.

The Tottenham Urban District Council is about to spend £4000 in works of sewerage.

The Hornsey Urban District Council proposes spending a further sum of £13,600 in works of sewerage and surface-water drainage.

We understand that the tender of Messrs. Bird and Pippard, builders and contractors, Yeovil, for the sewerage works, has been accepted at £14,180.

A Local Government Board inquiry was held at Rickmansworth last week into the application of the Urban District Council for sanction to a loan of £31,000 for sewerage and sewage disposal works.

The Sewerage Committee of the Aberdeen Town Council has accepted the offer of Mr. Roderick M'Kay for the extension of the sewer in Cranford-road at £461, also that of Messrs. Gall and Walker for the extension of the sewer in Walker-place at £26 odd.

Colonel Hepper held an inquiry at Freshwater last week on behalf of the Local Government Board into the application of the Rural District Council for a loan for carrying out Mr. Chatterton's scheme of sewerage, the cost of which is estimated at £24,000 odd.

We understand that the Newtownards Rural District Council has chosen Mr. E. L. Woods, civil engineer, Bangor, to prepare and carry out a scheme of drainage for Donaghadee. Mr. Woods, who is already well known as Town Surveyor of Bangor, was selected for this work out of a long list of competitors from all parts of the kingdom.

Application is to be made by the King's Norton Council for sanction of a loan of £1812 for a scheme of improved sewer ventilation throughout the whole of the Council's sewerage system within the Tame and Rea area, £1130 for improved sewer flushing by means of automatic flushing tanks, and £827 10s. for the reconstruction of defective sewers.

The Northern District Committee of the Ayrshire County Council has resolved to raise no objection to the proposed extension of Kilwinning Burgh. The reasons for wishing the extension are that the lands to be included are feuing lands; that they are already within the special water supply district; that the proprietors are desirous that they should be included; and that the drainage of a dwelling-house built thereon is already being conveyed into the burgh sewers, which is the only practicable means of drainage for that house, as well as for any other which may be erected on the lands proposed to be included.

At a meeting of the Glasgow Sewage Committee held last week, a report was submitted by Mr. A. B. M'Donald, the City Engineer, and Mr. W. Santo Crimp, Consulting Engineer, on the proposed widening of the river at Dalmuir. The report says that the effect of the present modified proposal is to cut off a strip of land belonging to the Corporation, which, in so far as it borders on the south of the intended sewage works, is about 50ft. in width, to which extent the land proposed to be utilised for the precipitation tanks and other arrangements will be curtailed. The reporters consider that it is most undesirable to begin any of the operations included in the contracts for which estimates have been received until the Committee is placed in unimpeded possession of the river frontage. The report was remitted to a sub-committee, to meet and endeavour to arrange matters with the Clyde Trustees.

A Local Government Board inquiry has been held at Tarporley into the application of the Urban District Council for sanction to borrow £4500 for purposes of sewerage and sewage disposal.

Mr. P. Boulnois held an inquiry at Congleton last week, on behalf of the Local Government Board, with reference to the application of the Council to borrow £16,900 for sewage disposal purposes, and £4703 for street improvements. It is proposed to deal with the sewage on the bacteria principle, and eleven acres of land have been provisionally secured. There was no opposition.

At a meeting of the Drighlington Urban District Council last week a communication was read from the Local Government Board in regard to the recent inquiry with respect to the erection of sewage disposal works and for sanction to borrow £12,660 for that purpose. The Board grants the issue of a Provisional Order, but defers for further consideration its sanction for a loan.

At a meeting of the Streets Committee of the Swansea Corporation last week the estimates for the year were produced. The amount totalled £26,997, against £25,577 and £21,747 in the two years last past, and in reply to the Mayor, who said the cost of the streets was being much complained of, the surveyor stated that the amount was not excessive to keep 74 miles of streets in repair. At a meeting of the Water and Sewers Committee it was stated that the amended scheme for sewerage for Brynmill would entail an addition of £13,000 to the cost by laying down a double set of pipes. It is understood the Brynmill outlet and septic tank system was decided on as against the alternative scheme of bringing the pipes up to the pier.

Up to the present time the sewage from the parishes of Winshill and Stapenhill in the Burton borough has been turned into the river Trent untreated. These two places have a population of about 10,300, and the number of inhabited houses is estimated at 2000. There has for some time past been public protest against this mode of sewage disposal, and at its meeting last week the Burton Town Council had under consideration an important report from the Highway and Sewers Committee recommending the adoption of a complete system of sewerage for the two places named, prepared by the Borough Surveyor, Mr. Lynam, and estimated to cost £47,500. The report was adopted with only three dissentients.

Col. Marsh held an inquiry at Haverhill last week into an application of the Urban District Council for sanction to borrow £1100 for works of sewerage. The Surveyor (Mr. J. J. Knewstubb) said that the application was the result of an attempt on the part of the Council to deal with some of the more important part of the sewerage of the town. For several years the immediate district embraced by the scheme had been particularly liable to infectious disease, alleged to arise in the main from defective sewers. Complaints had been continually made about the existing sewers getting blocked, overflowing into the river, flooding cellars, &c., until the Council had been compelled seriously to consider the question. After going very carefully into figures they were satisfied that the best and most economical way of dealing with the matter was to carry out the scheme upon which the present application was based.

Colonel Marsh, Local Government Board Inspector, held an inquiry at Sudbury last Friday with reference to an application of the Town Council for sanction to borrow £20,060 for purposes of sewerage and surface-water drainage —£15,536 19s. 8d. for sewerage and £4523 8s. for drainage. The Borough Engineer (Mr. T. W. A. Hayward) said the present system in the town was more designed for the purpose of carrying out domestic sewers; they were purely old surface-water drains. The number of houses and places in the town where drains would be connected was 1900. The Corporation proposed to connect all the house drains that were at present running into the surface-water drains, and also to connect all houses that were at present unconnected. Dealing with the details of the scheme, the Surveyor estimated that 160,000 gallons per day was the normal dry weather flow, and the basis of the calculation for the capacity of the sewers was six times the dry-weather flow. They were estimating the prospective population at 10,000. The size of all sewers had been decided upon very carefully, and in no case would any sewer run more than one-third full (Weisbach's formula) when carrying off

sewage at the rate of 120 gallons per head per day, thus making provision for when the sewers were running full. The gradients were so arranged that practically every sewer would have a self-cleansing velocity. Provision had been made in the estimates for five automatic flushing chambers, and for fitting up five manholes for use as flushing manholes.

WATER.

Last week the ceremony took place at Cowpe Reservoir, belonging to the Bacup Corporation, of cutting the first sod and laying the first stone of the new reservoir, which will cost £140,000. The sod was cut by Alderman Shepherd, and the first stone laid by the Mayor (Alderman Maden). Mr. James Diggle, of Heywood, is the engineer.

Mr. Goldsworthy, in bringing up the report of the Waterworks Committee at the monthly meeting of Newport County Council, said it was proposed to construct a small service reservoir near Christchurch at a cost of £6000 or £7000, including land, to reduce the water pressure. The outlay would be saved by the economy in the thickness of the main, which otherwise must be of a very strong specification.

At an ordinary meeting of the East and West Ardsley District Council, held last week, it was resolved that the clerk write the Hunslet Rural District Council respecting their complaint regarding the water, that the matter has been considered, and their communications have been forwarded to the parties from whom the water is obtained, and that the Council have also had an analysis taken, which does not agree with the assertions made by their Medical Officer.

For some time past the Water Committee of Crieff Town Council has had under consideration the improvement of and additional storage for the water supply of the town. At the end of last year Mr. Robert Gilmour, C.E., Glasgow, was instructed to examine and report on the whole system, and at the last monthly meeting of the Council his report was submitted, in which it was shown that the present reservoir on the Knock was too small. He, therefore, proposed the laying down of additional piping between Loch Turret and Crieff, the erection of filters and a new reservoir on Ochtertyre estate, capable of containing 2½ million gallons of water, equal to a five-days' supply for a population of 10,000. The recommendations of the engineer were approved, and the works will be proceeded with immediately.

On the second reading in the House of Commons last week of the Wolverhampton Corporation Water Bill, Mr. A. H. Brown rose for the purpose of moving its rejection. He contended that public rights must ordinarily take precedence over private rights. The case of Wolverhampton differed from that of many other towns, in that they had already, by legislation, ample means of getting water if they wanted it, and there was no necessity for the Corporation to come to Parliament for further powers. The opponents of this Bill contended that large interests would be seriously damaged by putting down the necessary works. The interest of landowners and proprietors of public works would be interfered with. If the necessary wells were put down, all the money expended by other authorities in obtaining a supply would be practically wasted, and the taxpayers would be saddled with a heavy burden.

A meeting of the Water Committee of the Arbroath Police Commission was held last week. The Clerk (Mr. W. F. Mackintosh) read a lengthy report by Mr. M'Culloch, C.E., regarding financial matters connected with the Nolt Loan extension scheme. The statement showed that the total claim of Messrs. Patterson, Limited, Glasgow, the contractors for the work, amounted to £12,518 7s. 11d. The Commissioners' engineer, however, valued the work done at £5169 1s. 6d., of which sum the Commissioners had paid to account £5000, leaving a balance due to the contractors of £169 1s. 6d. If, however, it were the case that the work had not been carried out according to contract and in the specified time, the engineer brought out that, in place of the Commissioners being due the contractors the sum of £169 1s. 6d., the latter are actually due the Commissioners a total of £3570 19s. 3d.

A Local Government Board inquiry has been held at Shifnal with reference to an application by the Town Council of the Borough of Wenlock for sanction to supply water to the rural district of Shifnal for the benefit of the contributory places of Badger, Beckbury, Kemberton, Shifnal Special Drainage District, Shifnal, Stirchley, Stockton, and Sutton Maddock.

Last Thursday the Waterworks Committee of the Manchester Corporation had under consideration matters relating to the laying of a second pipe from Thirlmere to Manchester. The first contract for pipes has been let, and the second and third are now being dealt with. Tenders for the fourth and last lot required remain to be invited. When this has been done the tenders for laying the pipes will be considered. It is expected that the work will be commenced in the early summer. The section lying between Prestwich and Hoghton Tower, near Preston, is the first to be undertaken. The Committee intends to offer a strenuous opposition to the Bill which the Salford Corporation is promoting in the present session of Parliament with the object of getting the supply of water to its borough on more favourable terms.

At the last monthly meeting of the Edinburgh and District Water Trustees the engineer was authorised to present Sir John Murray, K.C.B., with a copy of the lithographed sheets of plan and cross-section of St. Mary's Loch in connection with the investigations being carried on by him for scientific purposes regarding the depth and areas of Scottish lochs. A letter was submitted from the town clerk of Musselburgh in regard to the supply of water to Musselburgh and Inveresk, enclosing a report by Messrs. Belfrage and Carfrae, C.E., as to the existing and proposed improvement of the supply, and requesting a conference with the trustees on the subject. The report stated that by agreement with the Trust it was provided that Musselburgh and the Inveresk Local Authority should have a preferential supply of 360,000 gallons per day to be delivered in bulk to Musselburgh and the special water district of Inveresk before Portobello or other places near to or on the line of main pipe between Cameron Toll and New Craighall were supplied. The report was sent to the engineer.

At the last monthly meeting of the Largs Town Council a report was submitted from Mr. W. R. Copland, C.E., Glasgow, on the matter of extending the present reservoir at Middleton. Mr. Copland reported that to extend the reservoir as far north as possible would give additional storage for 1,330,000 gallons, at a probable cost of £1010, equal to £750 per million gallons; to extend it and raise it 3ft., would give 6,300,000 more gallons, at a probable cost of £4400, or £698 per million gallons; while to raise it 5ft. would give 16,000,000 gallons, at a probable cost of £6800, or £425 per million. These prices did not include the cost of land, and the cost was on the assumption that the puddling of the present embankment would be sufficient for the increased height. If this was not so the cost would be materially increased to probably £8000. On the other hand, the proposed new reservoir on the Noddle was proposed to provide 44,000,000 gallons extra storage at a cost of £8000, or £182 per million gallons. The matter was left over till next month to allow the councillors to consider the report.

LIGHTING.

The Long Eaton Gas Bill has passed the first reading in the House of Commons.

It is stated that the Bradford Corporation is making another effort to acquire the undertaking of the Clayton Gas Company.

The Local Government Board has sanctioned the application of the Burslem Town Council to a loan of £31,000 for the purposes of the gas undertaking.

Delegates from twenty-six different Scottish burghs met in the Religious Institution Rooms, Glasgow, last Friday, for the purpose of considering the Bills that are being promoted by the Clyde Valley Electrical Power Company and the Caledonian Power Company. The principal business of the meeting was to make arrangements for opposing in Parliament the Bills referred to, in the interests of the different burghs.

A PETITION on behalf of the Nottingham School Board, praying to be heard by counsel against the Corporation Gas Bill, when the Committee stage is reached, has been deposited in the Private Bill-office of the House of Lords.

AN official notification has been given that the Bill promoted by the Newcastle-upon-Tyne and Gateshead Gas Company will pass as an unopposed measure through the House of Lords, no petitions having been presented against it within the time allowed by the Standing Orders.

THE Abingdon Gas Company has made a trade profit of £1900 on the year, and the dividends for the year are £6 10s. and £4 11s. on the two classes of shares. The quantity of gas sold was nineteen millions, an increase of one million and a-half cubic feet. The installation of new regenerative furnaces obviated the necessity of raising the price of gas in consequence of the increased cost of coal.

A BOARD of Trade inquiry was held at Caterham last week into the application of the Caterham and District Gas Light and Coke Company for powers to extend their area so as to include the parish of Woldingham, and for the erection of two gasholders in the chalkpit situate at the rear of the Public Hall, Godstone-road, Caterham Valley. Considerable opposition came from the residents in the vicinity.

THE annual report and statement of accounts of the Leamington Priors Gas Company has just been issued. The directors recommend that the usual dividend of 10 per cent. on the A shares, and 7 per cent. on the B shares, less income tax, be paid. A majority of the shareholders have expressed themselves desirous of allowing the Leamington Corporation to withdraw from the purchase of the gasworks, and the matter is now having the serious consideration of the Board.

A NEW system of electric lighting is being tried experimentally in several carriages of the London and South-Western Railway, and should it prove successful the scheme will be generally adopted. Each compartment is to be fitted with four lamps, whilst one switch (which will be under the control of the guard) will serve a whole carriage of about eight compartments. The lamps are placed in convenient positions, so that passengers occupying corner seats will be enabled to read with the same degree of comfort as others in the compartment.

THE Mayor, Captain Gerald Walker, presided at a general meeting of the Richmond Town Council last week, when a lengthy report was read from Mr. John Wright, manager of the gasworks, giving the result of a general inspection of the gas mains throughout the town. The investigation showed leakages estimated to lose 1,224,340 cubic feet per annum. The cause of the leakage was attributed largely to defective mains and services. The leading mains had been laid thirty years, and over £3000 had been expended. He recommended all old and small mains and services should be replaced by larger ones. The meeting adjourned for a fortnight.

AT the Westminster Town Hall, on Thursday last, the inquiry by the Board of Trade to consider the application of various electric lighting companies and Local Authorities for an alteration of the regulations for ensuring a proper and sufficient supply of energy was resumed. At the sitting on Tuesday the following new proviso was put forward as a basis on which the parties might agree:—"Provided that no change shall be made in the pressure of the supply to any premises which on . . . . were supplied with energy by the undertakers except with the consent of the consumer; but, where the consumer withholds his consent after the undertakers have offered to pay the reasonable costs of or incidental to the change, the undertakers may appeal to the Board of Trade, and that Board may, if they think fit, dispense with the consent of the consumer on such conditions as the Board impose." Mr. Gunyon, in charge of the Electric Lighting Department of the London County Council, said that in his opinion the proposed change would not confer any benefit on the consumers; in many cases they would be the losers. If the pressure were put up to 200 volts the susceptibility to fire would become greater. If more pains were taken in the fittings and in the installation generally the risks were not so great. The proposed change would mean increased cost of all lamps, shorter life, less efficiency, and increased danger of fire.

THE Gas Light and Coke Company's Bill came up for second reading in the House of Commons last Thursday night. The brief discussion which took place showed, however, that there was not the slightest chance of its success, and to avoid a formal rejection it was withdrawn.

MR. HAWTAYNE, the Lowestoft Corporation's consulting electrical engineer, has presented the Council with a scheme for extending the light to all parts of the town, which the Corporation has affirmed. The scheme includes the providing and connecting of 526 new posts, of which 200 would be fitted with 32 candle-power lamps, and 386 with 16 candle-power lamps—say, six switching points complete with all accessories, £9550. All necessary road work is provided for in the estimate. The annual cost of lighting under the scheme, including interest and sinking fund at the rate of 5¼ per cent. on the capital outlay, is £1836 17s., or £2 14s. 6d. per annum each 16 candle-power lamp, and £3 18s. 6d. per annum for each 32 candle-power.

GENERAL.

THE Stockport Corporation is acquiring for £14,000 a site for the erection of municipal offices.

THE Brentwood Urban Council's scheme for the erection of from thirty-four to thirty-six cottages, under the provisions of the Housing of the Working Classes Act, at an estimated cost of between £6000 and £7000, has been cordially approved by the ratepayers of Brentwood in public meeting.

DR. GEORGE REID, Medical Officer of Health for Staffordshire, gave evidence last week before the Royal Commission on arsenical poison in beer. As to preventive measures, his suggestions included one that the Inland Revenue Department should be called upon to exercise control over the quality of brewing materials from a health point of view, by its being made part of the duty of Excise officers to see that a guarantee of the sugar used is obtained, and to periodically collect samples of materials for analysis by Somerset House.

LAST Friday afternoon two additional blocks at the Crossley fever hospital, belonging to the Mirfield and Liversedge District Councils, were formally opened for the reception of typhoid fever patients. Originally the hospital was confined to the treatment of cases of scarlet fever, but the prevalence of typhoid at Liversedge some time ago resulted in the two new blocks being attached to the present structure. The building, although only a temporary structure, is most comfortably furnished and fitted up with the latest appliances, the cost amounting to £1600.

AT a recent meeting of the governors of the Dundee Royal Infirmary the chairman referred to the treatment of consumptive patients in the shelters recently erected in the infirmary grounds. He said a number of patients had been treated under the new system. It was found that they markedly improved, and a considerable portion of them were able afterwards to undertake light employment. An excellent moral effect was produced, as the patient gained encouragement and came to know that his health lay largely in his own hands, and endeavoured when he returned to his home to carry out the principles he had learned, namely, the importance of fresh air, sunlight, and nourishing food.

A GREAT advance in the sanitation of West Hartlepool is expected to date from the time when the new refuse destructor gets fairly and fully to work. Hitherto the refuse has had to be carted out of the town, a process which has been found both tedious and costly. With the destructor at work more expeditious and effective treatment is anticipated. The destructor is one of the Horsfall Furnace Syndicate's, with patent furnace, and has been constructed under the superintendence of Mr. J. W. Brown, the Borough Engineer. It consists of six cells, each capable of burning 12½ tons of night-soil refuse in twenty-four hours, or a total of 75 tons. There are two tubular boilers, and the heat evolved is guaranteed to evaporate 1 lb. of water to every pound of refuse burned. The surplus steam, it is expected, will be profitably used in connection with the electric lighting station, which occupies the adjoining site.

Mr. M. K. North, Local Government Board Inspector, held an inquiry at Burnham recently into an application by the Urban District Council, to borrow £1200 for the erection of a bandstand, shelter, and public conveniences on the sea front.

At a meeting of the Tobermory Town Council last week Mr. Neil Macdonald submitted plans for an extension of the infectious diseases hospital in the vicinity of the town. He was of opinion that to execute repairs on old buildings would be throwing money away. At present the old building, purchased from a former Parochial Board, would be fitted up to the satisfaction of the burgh Medical Officer for the reception of patients. The extension proposed by Councillor Macdonald would cost from £800 to £1000. A petition from butchers in the town was presented, pointing out that the sewage from the infectious diseases hospital, as intended to be carried out at present, would pollute the stream passing in close proximity to the slaughter-house.

PERSONAL.

Mr. Ponsford Cann has been appointed Medical Officer of Health for Newhaven.

Dr. Sutton has been unanimously re-elected Medical Officer for Sittingbourne.

Dr. Bond has been re-elected Medical Officer for Westbury-on-Severn for another year.

Mr. C. D. Taite, of Southport, has been appointed chief Electrical Engineer for Salford.

Mr. R. Hilton, of Blackburn, has been appointed Town Clerk for Swindon at a salary of £500 per annum.

Mr. G. Pine has been appointed Assistant Sanitary Inspector for Dover at a salary of £2 2s. per week.

Mr. Harper has been reappointed Medical Officer of the Bath rural district at a salary of £160 per annum.

Mr. Amos D. Shrives has been reappointed Sanitary Inspector for the urban district of Farnborough, Hants.

Mr. A. J. Saise has been appointed Inspector of Nuisances for the Uurban District of Kingswood at the same salary.

Dr. Gale has been reappointed Medical Officer of Health, and Mr. S. Jump, Inspector of Nuisances for Norton.

Mr. R. S. Downe, of Liverpool, has been appointed Electrical Engineer for Southport at a salary of £350 per annum.

Mr. Monckton has been reappointed Medical Officer of Health, and Mr. F. H. Smith Inspector of Nuisances for Portishead.

Dr. Smith, of Crawshawbooth, has been appointed Medical Officer for the Rawtenstall borough at a salary of £100 per annum.

Mr. C. V. Hitchins has been reappointed Medical Officer of Health for Weston-super-Mare at an increased salary of £125 per annum.

Dr. W. M. Hamilton, J.P., has been appointed Medical Officer for the Borough of Eccles at a salary of £150 per annum, consequent upon the resignation of Dr. Crocker.

Mr. T. H. Scott, of Edinburgh, has been appointed Burgh Surveyor, Sanitary Inspector, and Water Engineer for Peterhead, in room of Mr. J. Chisholm, appointed to Airdrie.

Dr. John Aitken, Medical Officer for Buckhaven, Methil, and Leven, has been appointed Medical Officer for the borough of Bo'ness during the absence of Dr. Marshall, who has gone to South Africa to act as a civil surgeon.

We understand that Councillor Elliot and Dr. Templeman are to represent Dundee in London at the British Congress on Tuberculosis, and at Eastbourne, where the Royal Institute of Public Health Congress is to be held.

At a recent meeting of the Tenby Town Council a letter from Dr. John Griffith Lock was read, resigning his office of Medical Officer of Health for the borough, which he has held under the Corporation since 1872. Dr. Lock has suffered from ill-health.

Mr. Gerard J. G. Jensen, C.E., it is announced, will give a lecture on "Notes on Domestic Cold Water Supply," at Bury, Lancs, on the 28th inst. The lecture will be given for the Manchester and District Council of the Worshipful Company of Plumbers, and will be delivered in the large lecture-room of the Bury Technical School.

The Finance Committee of the Hampstead Borough Council has reported that Mr. C. H. Lowe, the Surveyor and Engineer, desires to retire, on account of his age and the extra duties he would have to perform under the London Government Act. He was appointed Surveyor of Hampstead in 1871, at a salary of £300 per year, increased to its present figure of £730, and the Committee had made him an offer of an increase to £800 if he had been willing to stay in the Council's service.

LAW CASES.

Houses Built with Insanitary Mortar.

At Cannock, Herbert Foster, of Five Ways, was charged under the Public Health Act with a breach of the bye-laws of the Cannock Urban Council, by erecting some houses at Blackfords with mortar made with water mixed with sewage matter. Evidence was given that in the erection of the walls water had been used taken from a cesspit, into which the sewage from several houses flowed. Notices to pull down the walls had been disregarded and the building continued. The Surveyor said the mortar would be full of bacteria. The Bench said that mortar made with sewage matter must be injurious to health, and made the order to demolish the houses, with costs. As it was a serious matter for the defendant, no penalty was attached.

Failing to Notify Scarlet Fever.

At the Leicester Police-court, Henry Smith, watchmaker, Hathern, was charged with failing to notify scarlet fever in his house on February 12th.

Mr. A. W. Jarratt prosecuted on behalf of the Loughborough Rural District Council, and said that the case was taken under the Infectious Diseases Notification Act. The defendant lived with his wife and seven children, and all of these children had been affected with the disease. In consequence of three of them being away from school the officer visited the house and found that they were suffering from scarlet fever. He reported the case to the Sanitary Inspector, who gave instructions, which were not complied with, as the children were sent on errands, which was a further offence against the Public Health Act. The Rural District Council did not wish to punish the defendant severely, as he was in very poor circumstances. The case was brought with the object of warning others, and bringing before parents their responsibility in the matter.

Mr. Harris, the School Attendance Officer, said that when he called at the house on the date named the defendant said the children were ill, and that he had them all in one room to keep them warm. He further said they had scarlet fever, and the reason he had not notified it was because he did not want to make any bother. He had had a case before.

Edward G. Churchill, Sanitary Inspector to the Rural District Council, spoke to visiting the house, and seeing the children. They were in the "peeling" stage. He gave instructions for isolation and other directions, but these were not carried out, the children having been sent on errands.

Dr. Corcoran, the Medical Officer, said he saw five of the children on whom every symptom of the disease was well marked. They were typical cases. A case had since broken out next door but one to the defendant.

The Chairman said that defendant would be fined 10s., or five days in default. But for what Mr. Jarratt had said, they would have put the extreme penalty upon the defendant. The Magistrates all felt it was a serious thing, and ought to be dealt with as severely as it lay in their power.

Defendant did not appear, and it was stated that he was ill.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2123.—Footways: Tar-paving: Materials and Thickness.—"Assistant" writes:—(1) "Would you consider a thickness of 2½in. (say 1½in. bottoming and 1in. topping), for a tar-paved footpath, in a street where there is not very heavy traffic, sufficient? (2) Would it be sufficient to lay the material on a bed of engine ashes 1in. thick, or should the bed be of broken stone or brick 3in. thick? (3) Would it be safe to use this material for the paths of a street with a southerly aspect and having a gradient of about 1 in 8, or would the material "creep"? (4) Do you think such a footpath would be more slippery than if paved with York flags? (5) How should the side of the path be supported where it does not abut against a wall or the kerb?"

Answer.—(1) A thickness of 2½in. is usual and sufficient, the separate layers being as suggested. (2) If the foundation be of clean gravel no special preparation is necessary; otherwise a bed of ashes 1in. thick is sufficient. (3) It would be quite "safe" if the tar-paving material be properly made, and there should be no "creeping." (4) No. (5) By a row of ordinary granite setts or kerb, or by edging of 2in. by 4in. yellow deal let into the ground and secured by stakes 2in. by 4in., 1ft. in length, and 6ft. apart.

2124.—Offensive Trades: Nuisance from Burning Refuse.—"C. B." writes:—"In my district there are a number of persons who burn leather refuse, which gives off a very offensive odour from factory chimneys, and from such buildings as greenhouses. The smoke is not, however, black, and therefore Sec. 91 of the Act of 1875 does not apply."

Answer.—Proceedings may be taken under Sec. 114 of the Act of 1875.

2125.—Drainage of Basements and Cellars: Book Recommended.—"E. C." writes:—"Will you please recommend me a good book dealing with the drainage of basements, the floors of which are in some cases below the level of the sewer?"

Answer.—Spinks' "House Drainage," price 5s., is the best book we know of dealing with the subject. It describes how to drain ordinary basements, and also the method to be adopted for raising sewage from basements which cannot be drained into sewers by gravitation. The book may be obtained from the office of this journal.

2126.—Sanitary Acts for Inspectors; Dairies, Books on.—"L. F. S." writes:—"Being engaged in preparation for the Inspectors' examination of the Sanitary Institute, I find it very difficult to summarise the Acts relating to Sanitation. I should be greatly obliged by your informing me if there is such a publication and the price of same. I am also desirous of obtaining a book of sketches of buildings showing the method of construction and draining of a model dairy."

Answer.—The querist will find in Reid's "Practical Sanitation," price 6s., and also in Stockman's "Practical Guide for Sanitary Inspectors," price 5s., an epitome of so much of the law as affects the duties of Sanitary Inspectors. The latter book, in our opinion, will be found the best for the purposes required. Dudley Clarke's "Farm Buildings: their Construction and Arrangement," price 7s. 6d., is the best book we know of dealing with the construction of dairies. Any of the books may be obtained from the office of this journal.

2127.—Nuisance Arising from Absence of Dampcourse: Proceedings.—"Andentes" writes:—"In this district there are some old houses without dampcourses. The walls are very damp. They are not sufficiently bad to be dealt with as unfit for habitation, and it is desired to get dampcourses put in. Can the owner be compelled under Sec. 91, Sub-sec. 1, or other section of the Act of 1875, to put in dampcourses?"

Answer.—Where the walls of a dwelling-house are very damp, as in the case stated by the querist, their condition renders the premises in such a state as to be a nuisance or injurious to health, as defined by Sub-sec. 1 of Sec. 91 of the Act of 1875, and the Local Authority may, by notice served under Sec. 94, require the owner to abate the nuisance by inserting a suitable and sufficient dampcourse, and on his default they may institute proceedings under Secs. 95 and 96.

2128.—Dairies, Cowsheds, and Milkshops Order: Application of.—"Ajax" writes: "Would a person keeping four cows and selling the milk in pennyworths and half-pints, and only supplying his neighbours, come within the provisions of the Order? If so, would his cowshed have to conform to the Model Regulations which are in force in the district, and will he come within the provisions of the Order at all?"

Answer.—As to whether the milkseller comes within the provisions of the Acts, this cannot be determined without a knowledge as to whether the cows are kept mainly for his own use, and the surplus milk is only sold, or whether the cows are kept for the purpose of profit, and whether the whole of the milk obtained therefrom is sold. If the latter, then the Order will apply, and the cowshed should be registered and the Regulations complied with. If the former applies, then the Order and Regulations will not be applicable.

STANLEY
Government Contractors.
Makers of Mathematical, Drawing and Surveying Instruments of every Description.
Gold Medals at the Great Exhibitions. Catalogues post free.
Addres W. F. STANLEY & CO., LTD.,
Great Turnstile, Holborn, London, W.C.

Late Chemist and Superintending Gas Examiner to the Metropolitan Board of Works and the London County Council.

(*Continued from page* 224.)

CHAPTER XVII.—MEASUREMENT OF CURRENT.

THREE-WIRE SYSTEM.

While examining the course of a current in a circuit it may be as well to describe the system of wiring for continuous currents, known as the "*three-wire system*," which is being largely adopted at the present time, as it enables higher voltages to be used and twice the number of lamps to be lit with very little extra expenditure in the wiring.

As we have already mentioned, the voltage of the current used for lighting with incandescent lamps may not exceed about 220.

The voltage of alternating currents can be easily and economically raised or lowered, even on a small scale, by means of transformers; but this is not the case with continuous currents, where a transformer can only be economically used in a large installation.

It is, of course, always possible to connect lamps in series, and on the Central London Railway, where the voltage of the current is about 500, five incandescent lamps are connected in series, so that the voltage between the positive and negative terminals of each lamp is only 100. This system, however, is only practicable in exceptional cases, as, besides other disadvantages which it possesses, the five lamps in series must necessarily be inseparable; so that if one is alight all must be alight, and if one burns out or is otherwise extinguished, all will be extinguished. For this reason lamps should always be connected in parallel if possible, in order that any lamp may be switched off without disturbing the rest.

An installation on the three-wire system requires two generators connected in series; or the same effect may be produced with one generator having a double armature, with two commutators and two sets of brushes, but the connections would be the same in either case. Fig. 33 shows the arrangement.

By adopting this system a voltage of, say, 220 can be used for lighting, and 440 for motive purposes, with the advantage that the wires need only be large enough to carry current at 440 volts pressure.

It will be seen that wire *a* leads from the positive terminal of dynamo I, and wire *c* leads to the negative terminal of dynamo II, while wire *b* is neutral; and may conduct current to dynamo I, or from dynamo II, as shown by the dotted arrows on the diagram, according to which side of the circuit requires more current than the other. Examining the course of the current along the whole circuit, it may be assumed that dynamo II generates a current of, say, 220 volts, passing on to dynamo I, which, being wound the same as dynamo II, also generates a current of 220 volts; but as the two dynamos are connected in series, the current passing from one machine to the other is doubled in voltage without increasing in ampères.

An admirable representation of this may be seen in our air pump, Fig. 31, where the back of the piston represents the negative terminal of dynamo II, and the front of the piston the positive terminal of dynamo I, while the wires *a*, *b*, and *c* are represented by the different portions of the pump *a*, *b*, and *c* respectively.

Just as the pressure of the air in the pump at *a* is + 1 lb., at *b* neutral, and at *c* − 1 lb., with 1 lb. difference of pressure between *a* and *b* and between *b* and *c*, and 2 lb. difference of pressure between *a* and *c*, so in the circuit Fig. 33 we have a potential of + 220 volts at *a*, − 220 volts at *c*, and a neutral wire *b*, with a difference of potential of 220 volts between *a* and *b* and between *b* and *c*, and a difference of potential of 440 volts between *a* and *c*.

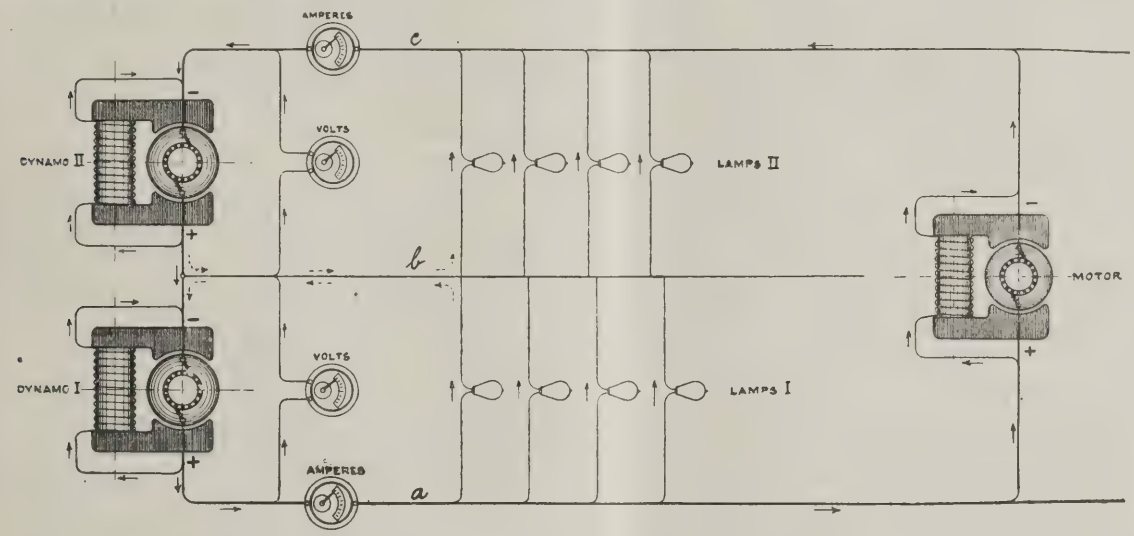

Fig. 33.

The two sets of lamps I and II are merely connected in series; and, if both sets require the same amount of current, no current at all passes along the wire *b* to or from the generators.

But if there were no connection between the wire *b* and the generators, supposing one of the lamps I burned out or otherwise became disconnected, it would at once affect all the lamps II, which would burn very dimly, because the amount of current which the resistance of the three lamps allows to flow through when distributed over the four lamps would be insufficient, but having the wire *b* connected with the generators, the tendency would be for dynamo II to at once yield a sufficient extra amount of current; which, instead of flowing through dynamo I, would flow along wire *b* and through the lamps II to *c*.

In the same way, if one of the lamps II were disconnected, dynamo I would yield an extra amount of current, which would flow from its positive terminal, through the lamps I and along wire *b* to its negative terminal. Thus it will be seen that wire *b* conducts either positive or negative current, and only as much as the difference between that required for lamps I and II; so that very little current ever passes

through it, and only a comparatively thin wire is required.

The difference between the amount of current registered by the ammeters at *a* and at *c* is that which flows along wire *b*.

Motors may be connected from wires *a* to *b*, or from *b* to *c*, in which case a current of 220 volts is supplied to them; or they may be connected, as shown in the diagram, from wires *a* to *c*, thus supplying them with a current of 440 volts.

It is, of course, desirable to keep the resistances on each side of the circuit as nearly equal as possible, in order that both generators may have an equal amount of work to do, and that very much current may not pass along wire *b*, thus necessitating a large sectional area of metal.

(To be continued.)

SANITATION OF THE PORT OF LONDON.

In his half-yearly report on the work of port sanitation, Dr. Collingridge (the Medical Officer of Health for the Port of London) states that during the period under review 15,562 visits of inspection were made to vessels of all classes, 7626 lying in the river and 7936 in the various docks at the time of inspection. Of these, 1230 (equal to 7·8 per cent.) required cleansing. Of the vessels 7938 were from "foreign" ports, and 7624 "coastwise." Of the total number, 12,126 (equal to 77·92 per cent.) carried the British flag, the Norwegian coming next in order of number with 1598 (equal to 10·26 per cent.). Twenty-four sick seamen were referred to hospital on account of non-infectious disease. Structural alterations to the number of 171 were carried out for the improvement of sanitary conditions, these alterations affecting 156 vessels. With respect to barges carrying cargoes injurious or dangerous to the health of those on board, notices were served upon the owners to carry out improvements in order to secure the safety of the crews. The system of medical inspection carried out at Gravesend in conjunction with his Majesty's Customs resulted in 5472 vessels being visited by the boarding Medical Officers. Of these 554 were medically inspected, this process involving the personal examination of 10,124 passengers and 26,940 persons forming their crews. At Sheerness the boarding Medical Officer medically inspected 163 vessels, the previous half-year showing 100 such inspections. In reporting on the outbreak of the plague at Glasgow, Dr. Collingridge refers to the complete arrangements made at the Port of London to cope with any emergency in that direction. The result of the medical inspection of vessels was the removal to the Port Sanitary Hospital of 30 cases of infectious disease, but during the last six months 184 cases were dealt with, comprising one case of cholera, 4 cases of actual or suspected plague, one case of small-pox, 81 of enteric, 19 of diphtheria, 10 of scarlet fever, 56 of measles, and 12 of other diseases. Dr. Collingridge alludes also to a question that was raised by the War-office some months ago with reference to the ordering ashore at Gravesend of some soldiers suffering from enteric fever, who were returning from South Africa. The Military Authorities, at the conclusion of a conference on the subject, admitted that such cases had been rightly removed by the Medical Officer acting under the powers of the Public Health Act. The practical result of the concession is that the cost of maintenance of such cases will fall upon the Government, and not upon the Corporation. During the half-year 40 cases were admitted into the hospital, the total number of days' treatment being 968, and the average number of days for cases (including fatal ones) 21. The average number of patients per day was 5·3, while the average daily cost of maintenance (food and drugs only) was 1s. 8½d. per head. During the last year the officers inspected 655 canal boats within the limits of the port, and these, while registered to carry 2022 persons, were inhabited by 1276 at the time of inspection. In reporting upon condemned food, the Doctor states that, as the work of inspection continues to increase, he proposes to suggest to the Committee an increase of the staff engaged on that important duty.

NEW BYE-LAWS IN SYDNEY.

A number of bye-laws for promoting public health and public decency, for the suppression of nuisances in the city of Sydney, and for other purposes, have recently been issued. The bye-laws, which are very stringent, were sent for approval by Sir Matthew Harris (who fought determinedly to have them passed into law) in November last, and will give the City Council powers, which in the the interests of public health, have been sorely lacking for some years. The bye-laws for the promotion of public health gazetted on September 5th, 1881, have been repealed in favour of those now published.

Amongst the most important are those which provide the following:—

No person shall keep live poultry on any premises in the city, under such conditions as to create a nuisance, or to be dangerous or injurious to health.

No person shall place, throw, or leave any refuse on any premises in the city in such a manner, or for such a time, as to have a tendency to encourage rats or other vermin to visit or frequent such premises.

The owner of any stable, cow-yard, or cattle-shed in the city now constructed, shall cause the same to be paved, flagged, or floored with stone, asphalt, or other material impervious to wet, and to be completely and well drained, and to have proper sewerage connections where available, within one month after service upon him of a notice by the Inspector of Nuisances requiring him so to do.

The occupier of any factory in the city shall, within one month after service upon him of a notice by the Inspector of Nuisances requiring him so to do, cause the smoke arising from the fuel used in the fireplace, stove, or furnace connected with the chimney of such factory to be consumed, as far as practicable, in such chimney.

The occupier of any premises in the city other than a factory, from the chimney of which smoke, noxious fumes, or other matter issue to such an extent as to be a nuisance to the surrounding neighbourhood, shall, within fourteen days after service upon him of a notice by the Inspector of Nuisances requiring him so to do, cause such nuisances to be abated.

No keeper of any second-hand clothes shop shall in the city sell or expose for sale any second-hand clothing unless the same shall first have been thoroughly cleansed or disinfected, and in any proceeding under this bye-law, the onus of proving such cleansing or disinfecting shall be upon the person charged.

Every occupier of premises in the city shall provide and maintain in good order and condition a sufficient number of boxes or bins for the reception of garbage and refuse arising upon such premises, each of which as to material, shape, and size, when filled, shall be reasonably portable by one man, and shall be furnished with a suitable cover; and such occupier shall cause all garbage and refuse arising upon the premises from time to time to be deposited therein, and such boxes or bins to be continuously covered and to be so placed or kept as to be conveniently accessible to the persons engaged in the removal of garbage in the city.

Bye-laws regarding public conveniences are also included in the list. The penalties for any offence under the bye-laws range up to £10.

THE INSTITUTE OF SANITARY ENGINEERS

(Incorporated).

OFFICIAL TRANSACTIONS.

The fifth sessional meeting of the above was held at the Offices of the Society, 64, Chancery-lane, W.C., on Wednesday, March 13th, when the following paper on

"THE CLEANSING OF CESSPOOLS,"

was read, and specially-prepared drawings exhibited, by Mr. A. Taylor Allen (Fellow).

INTRODUCTORY.

I am perfectly aware that a system for the main drainage of towns is one of the important subjects which is undergoing rapid development towards perfection, and that there is a great advantage in having one common outfall, but the fact remains that the drainage of many small towns, villages, hamlets, and detached houses are still drained on what is known as the cesspool system, and in some cases, owing to the question of an outfall, engineering, or other difficulties, which has to be grappled with, a main drainage scheme is delayed, and in the meantime cesspools are predominant.

Owing to the formation of Parish Councils throughout the country more direct interest is taken in sanitary matters by the inhabitants of villages, and more active measures are being taken by Rural Authorities, so I think it is well that we as an Institute, representing various public bodies, should discuss the least objectionable and best sanitary method of cleansing existing cesspools, as upon its thoroughness the health of the district mainly depends.

In this paper I do not propose to deal with the construction of cesspools, but specially as to the cleansing of existing cesspools, and in alluding to a system of emptying that meets all reasonable objections I must ask you to be good enough to accept my remarks and drawings relating to a particular plant, as being given from actual experience with its working, as I do not wish to be considered an advertising medium.

To illustrate my paper I have specially prepared drawings, showing front and back view of several houses in my district, erected before the adoption of bye-laws, which possessed until recently—when the main sewer was extended along the street—a cesspool in each backyard, the only means of access to same being through the house, the estate being so developed as to deprive several houses of a back entrance. This is an exceptional case, I am pleased to state, but I have chosen it to illustrate that a cesspool can be emptied where no back passage exists, without the otherwise spilling and splashing of offensive matter through the dwelling-house, which, previous to my taking up my appointment, was the case, the work of cesspool emptying being carried out in a very unsatisfactory and filthy manner, and I was instrumental in the Council themselves undertaking to empty and cleanse cesspools wherever they existed in the district, out of the rates, on the system explained in following sections. At the time of writing my paper the main-drainage scheme for the *whole* district is in working order, so that the work for the plant during the present year will consist of emptying every existing cesspool previous to being filled up and a connection made to the new sewer, afterwards I propose using the vans for flushing the sewers, as they are well adapted for this purpose, and the hose will be of service in flushing the sewers direct from the water hydrants.

STATUTORY POWERS.

Drainage into cesspools is permissible under Secs. 23 and 25 Public Health Act, 1875.

Under Sec. 42 every Local Authority may, and when required by order of the Local Government Board *shall*, themselves undertake or contract for the cleansing of cesspools.

Under Sec. 44, where the Local Authority do *not* themselves undertake or contract for the cleansing of cesspools, they may make bye-laws imposing the duty of cleansing on the occupier of the premises.

Sec. 47 provides that any person in any *urban* district who allows the contents of any cesspool to overflow or soak therefrom shall be liable to a penalty not exceeding forty shillings, and further provides that the Local Authority *shall* abate, or cause to be abated, every such nuisance, and may recover in a summary manner the expenses of so doing.

Here I wish to point out that the recovery of the expense of abating the nuisance under this section is from the *occupier*, but if proceedings be taken *under Sec.* 91, Sub-section 1 or 4, of the same Act, recourse is given against the *owner*.

Sec. 41 appears to me to be affecting nuisances arising from defective construction rather than from want of cleansing. There is yet another section in the 1875 Act referring to cleansing of cesspools. It is Sec. 40, "Every Local Authority *shall* provide that all drains, water-closets, earth-closets, ashpits, and *cesspools*, within their district be constructed and *kept* so as not to be a nuisance or injurious to health."

This section should receive much earnest attention, as it imposes a duty upon the Authority with reference to nuisances arising from *temporary* defects.

In districts where the Local Authority themselves undertake or contract for the cleansing of cesspools, under Sec. 42 of the 1875 Act, the fact that a daily penalty can be enforced upon a Local Authority failing (without reasonable excuse) to perform such work within seven days from the receipt of a written notice from the occupier thereof, is worthy of serious attention.

Sec. 27 empowers either *Urban* or *Rural* Authorities for the purpose of receiving, storing, disinfecting, distributing, or otherwise disposing of sewage.

(2) To contract for the use of purchase, or take on lease any land, buildings, engines, materials, or apparatus, either within or without their district.

PROCEDURE UNDER PUBLIC HEALTH ACT.

I think it will be generally admitted that the procedure necessary to be taken for the cleansing or overflowing of a cesspool is a long and troublesome one, and considerable tact is required by the sanitary officer, inasmuch as it is necessary for him to acquaint himself with the circumstances of the case; for instance, a mere overflow from a gulley at the upper end of the drain is not always an indication that the cesspool is full and requires cleansing.

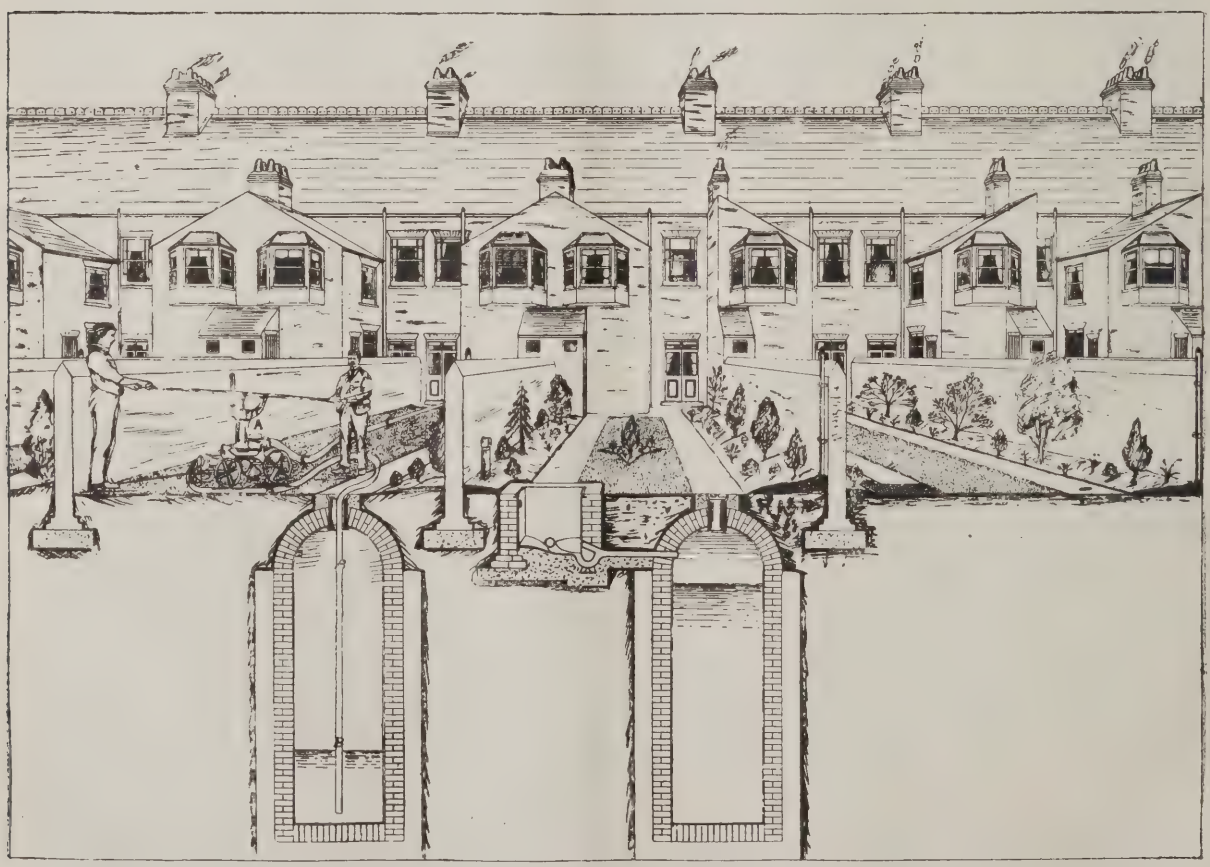
The form of notice usually supplied is necessarily copiously shown with "blanks," directions for filling up. In the operative part the following direction is given:—"Here specify any things required to be done or works required to be executed."

I have grave doubts whether a notice simply directing the owner or occupier (as the case may be) "to take such steps as may be necessary to abate the said nuisance" would be good and valid. It appears to me important that the notice should specify if the drains are to be cleared or the cesspool cleansed.

Failure to abate the nuisance, a complaint relating to such nuisance has to be made before a justice, who shall thereupon issue a summons; then the necessary information has to be obtained for the proceedings in a court of summary jurisdiction, and if the Court is satisfied that the alleged nuisance exists they shall make an order on such person, requiring him to comply with all, or any of the requisitions of the notice, or otherwise to abate the nuisance within a specified time. In the meantime the nuisance may exist, and the premises have to be visited to ascertain if the notice has been complied with; and what I wish to lay stress on is

"THE CLEANSING OF CESSPOOLS."

Emptying Cesspools of Houses having no Back Entrance—Front View.



Emptying Cesspools of Houses having no Back Entrance—Back View.

this: Has the notice been obeyed? The nuisance from an overflowing cesspool may have been abated, but has the cesspool been cleansed in the same manner, and as efficiently as the Local Authority would do it themselves if they undertook the work?

If the cesspool is a source of trouble and expense to the owner there is a possibility of his digging (unaware to the Authority) another cesspool in close proximity to the *ever-filling* one, and connecting the two by a few pipes. I am of strong opinion that the cleansing of cesspools should be as much the work of the Authority under Sec. 42 Public Health Act, 1875, as removal of house refuse under the same section.

In acting upon this principle it is, I think, clear that the district would be kept in a more sanitary condition, and instead of the officer having to find out when a cesspool was full, the occupier would gladly send him a notice to that effect.

OLD METHOD OF CLEANSING.

By the old method I do not mean that adopted by the owners of country residences and isolated houses in having a pump of simple mechanism construction fixed to the cesspool for utilising the contents on their own ground, but I refer more particularly to the usage of the carts known as "soil carts," which though a very primitive and insanitary mode, is still employed.

The plant consists of either a liquid-manure tank on wheels, or a tumbler cart suspended on the axle, so that it can be turned over to discharge its load by means of a rack and pinion, with wood or iron lids, and several buckets, with a rope or chain, and in some cases a ladder or a pump is employed. The buckets are filled and carried by the men to the cart, which remains open during the filling process, consequently the odour arising from this penetrates into the neighbourhood.

I think you will all agree with me that this system is one which should not be encouraged in the present day of sanitary reform, but that the consideration of a better scheme for cleansing cesspools is worthy of discussion.

ITS DISADVANTAGES.

(1) The cesspool cannot be emptied and cleansed without an opening being made, usually sufficiently large for a man to enter the cesspool; (2) the fact that a cesspool while being emptied must necessarily remain open for several hours; (3) the splashing of the sewage by the men in conveying the buckets from the cesspool to the carts and around the cesspool; (4) the danger the men are exposed to, and liability of their contracting disease; (5) the work being done at night time, when the proper supervision it should have is not forthcoming, owing to (*a*) insufficiency of light; (*b*) officials being off duty; (6) the non-guarantee of the cesspool being properly cleansed; (7) conveyance through dwelling-houses where no back entrance exists; (8) the unpleasant features, and considerable cost; (9) length of time occupied in emptying the cesspool (usually more than one night).

COST.

I know of owners who have paid as much as £6 on several occasions for emptying their cesspool.

Laxton, in his reliable Price-book, has given 16s. *per load* as a contract price for emptying cesspools. For a cesspool 3ft. 6in. diameter with 18ft. of sewage in it (1080 gallons or thereabouts), which would mean approximately six *loads*, as it must be borne in mind the old-fashioned soil cart cannot be filled, owing to the tilting and spilling of the contents, the cost would be £4 16s.

Allowing six gallons the minimum consumption of water for a household per day, and assuming the cesspool to be constructed under bye-laws approved by the Local Government Board (being practically water-tight), the cesspool would require emptying twice a year, costing the owner between £8 and £12 a year.

It is quite possible for an owner to be charged less, or secure a lower quotation for emptying his cesspool on this system, but to say that the contractor would guarantee, or the men stay long enough to empty the cesspool, is another matter. As a new cesspool could be dug and steined for £3 12s., it is only reasonable to expect that there would be a tendency among owners to dig and stein a new cesspool rather than to be continually emptying the old one.

(*To be continued.*

OLD WALL PAPERS AND THE DANGER OF INFECTION.

At a recent meeting of the Glasgow Corporation, Mr. Shaw Maxwell said he observed from the minutes that a letter had been read from the secretary of the Glasgow United Trades Council, intimating that at a meeting of that body complaints had been made by the painters' delegate of the manner in which (1) the houses of the working classes are re-papered, the old paper being simply covered over instead of being stripped off, and (2) closets are whitewashed without the walls being first washed down. He noticed that the committee agreed to allow the matter to lie on the table, but it seemed to him that these two suggestions were of an eminently common-sense character, and he would be glad to know why greater consideration was not given to them.

Mr. Dick replied that they had only powers in the case of infectious disease to compel parties to do so, and in the case of infectious disease they always insisted upon this being done. When it came to the others they had no powers, and they would require to get them when the proper time arrived.

Mr. Shaw Maxwell said it seemed to him that the time had come, and that the sooner they got the powers the better. He went on to call attention to a case in which a whole family of five persons had been compulsorily removed to the Weaver-street Reception Rooms, and inquired if this principle of compulsory removal applied equally to all citizens who might be in contact with the disease of small-pox, irrespective of locality, place, condition, or social position.

Mr. Dick, in reply, stated that if the Medical Officer of Health considered it necessary to do so, he had power to apply for a warrant. The family in question consented to their own removal before a warrant required to be applied for.

Mr. Jeffrey Hunter said he was not satisfied with the answer given by Mr. Dick in regard to the re-papering question. He thought the committee had treated this very important communication from the Trades Council in a rather cavalier manner. As Bailie Robt. Anderson knew, painters were the most careless class of tradesmen we had, and this vicious habit of putting on five or six papers, one on top of the other, should be discontinued.

Mr. Robert Anderson remarked that he had no desire to controvert what Mr. Hunter had so unwarrantably said regarding painters. It was sufficient that painters were always willing and desirous to do what they were paid for, but they had no intention of doing what they were not paid for. The onus of this particular evil lay on the proprietors. He had spoken to the convener in the forenoon regarding this paragraph, and had been assured by him that it was not the intention of the committee to allow this matter to drop, and he did not think they should allow it to drop. The number of five or six papers mentioned did not in any way represent the real state of matters in many cases. He had, in his own experience, seen seventeen papers taken off a wall: and there was no more fruitful source of infection, especially to painters, than the removal of those old papers, which might in years past have covered up infection.

PROBLEMS OF DOMESTIC SANITATION.*

By Dr. A. Inglis, M.O.H., Maybole.

There are two sides to almost every question of public health, as the following remarks will show, and these may be taken as fairly typical of the state of matters throughout the United Kingdom. Various circumstances, particularly the present widespread epidemic of small-pox, which is pretty general throughout the more populous portion of Scotland, and last year's outbreak of alleged plague have influenced the public mind in the direction more particularly of domestic sanitation. This very comprehensive subject includes the thorough renovation of all dwellings, which should be enjoined by statute upon proprietors, to be carried out at least every three or four years, or oftener where the particular circumstances necessitate. All passages should be whitewashed once in six months, woodwork should be scraped and painted afresh annually, kitchens should also be whitewashed every six months, and rooms re-papered every two or three years, unless the paper used be of a superior quality. In the matters of painting, whitewashing, and papering, no scamping should be permitted. Ceilings and walls should be thoroughly scraped before treatment. Per contra, the occupiers should also exercise diligence in the cleaning of rooms, stairs, and passages, and daily ventilation should be insisted upon. There are many tenants, and these often by no means of the poorest classes, who would soon turn a palatial residence into an insanitary pig-sty, to the hurt and nuisance of themselves and neighbours. There is need of a much more inflexible procedure with regard to uninhabitable houses than there has been in the past. The detection of insanitary conditions is frequently followed by the remonstrance—"But there have been no complaints made." The reason of this may sometimes be due to indifference on the part of the tenant, but more often is traceable to the scarcity of suitable houses for the industrial classes. This leads to a competition, a grim and awful struggle for existence, in fact, for the possession of a few putrescent and decaying shanties by those who can pay but a small rent, and the would-be occupier who makes the fewest complaints, and never asks for repairs, collars, of course, the prize, a state of matters truly pitiable in this age of civilisation—imperialism, expansion of territory, and overcrowding.

The thorough cleansing of courts, entries, and streets, is also important. The clearing away of waste paper, orange skin, and mud, which in bad weather collect and form a nidus of putrefaction, might well give employment to a casual labourer, armed with a broom, and anxious to earn a few pence by the job. This nuisance of expectoration upon the footpaths may, in dry weather, cause a dissemination of the tubercular bacillus, and is often as dangerous to the feet of the unwary pedestrian as orange peel. The nuisance can scarcely be effectually dealt with, until the great tribe of the Yahoo—alias Hooligan—which buttress up the street corners, and squirt the juice of rank tobacco to the obstruction and annoyance of peaceable citizens, are provided with suitable stanchioned residences in the nearest Zoological Gardens, as objects of curiosity to the intelligent foreigner. Not for the benefit of the Budget, but for the good of the very uprising generation, I would briefly mention the dangers of juvenile smoking, which impairs the physique and morals of five-year old men, who do not whistle as in the olden times on account of the obstruction caused by three-a-penny "fags." The sale of tobacco to persons under sixteen years should be prohibited by statute. The liberty of the subject must be regulated for the subject's own good. There can be no doubt that premature indulgence in alcohol or tobacco by weakening vitality, causes predisposition to heart disease and consumption.

It is alleged by many parents that the School Board is largely responsible for the spread of such diseases as measles and whooping-cough, by insisting on the return of scholars before they are free from the danger of giving infection. This is a matter which calls for investigation, with the object of either refutation or amendment, for measles and whooping-cough, although not notifiable, are nevertheless infectious diseases, and may sometimes be fatal to the very young. It is not enough to pass the matter over as mere "children's diseases." Small-pox was, a century ago, mostly a disease of children, and surely other infectious diseases as dangerous as, though more common now-a-days than, small-pox, merit at least an equal share of attention with the more exotic disease in regard to prophylaxis. In regard to other general matters affecting the public health, I would, for example, recommend that British barbers should adopt, for the benefit of themselves and customers, the antiseptic system used largely on the Continent and in some parts of America. Their razors, scissors, and other implements should be sterilised by passing these over a gas burner or spirit lamp. All brushes should be steeped in carbolic or other disinfectant solution, and each customer should have a clean boiled napkin or towel around his neck. The importance of these measures cannot be gainsaid.

There is a good deal of reason in some remarks lately appearing in the lay Press as to the construction of men's waistcoats, these being a front of good cloth and a back of some flimsy and inadequate material. This is utterly opposed to all principles of rational dress, both from the hygienic and common-sense point of view, as the coat, being frequently worn open across the chest, cold air finds its way round to the back, setting up in many instances pulmonary complaints—lumbago, rheumatism, and many of the other ills which flesh need not necessarily be heir to. The inspection and analysis of milk and the penalties frequently following thereon, are indeed excellent moves towards receiving the pure article; but how often are these measures simply and absolutely nullified by the consumers themselves. In spite of the proud boast that "Britons never shall be slaves," it is to be feared that many of the brave and the free are at times "Led willing captives of the giant sloth," so that, instead of a clean and possibly scalded receptacle for the lacteal fluid, there is often a residuum of the milk of other days in the bottom of the jug. This, with a few hours' stay in an overheated and presumably malodorous kitchen, would quickly sour the sweetest milk fresh from the cow, and might well account for infantile diarrhœa, with the usual remark that "the child is not thriving," until its sufferings are finally and mercifully ended. I am of opinion that leaflets distributed to the public as to the method of storage of milk might not be in vain.

It is also asserted on the best medical authority that the Sacramental cup may be an unsuspected means of spreading such diseases as tuberculosis, which consequences attending the use of a cup passed round in common were surely never intended by the Almighty, especially when it is borne in mind that many of the old Mosaic laws were founded on a sanitary basis. It is suggested that the dispensing of the wine in capsules would fulfil the provisions of the ordinance, and that without giving offence to anyone concerned. In a word, careful observance of the laws of health, moderation in all things, especially in eating and drinking, regular outdoor exercise, frequent bathing and other ablutions, healthy homes, and the maintenance of these in such condition and the inculcation of these things upon children, both by precept and example, will tend towards the perpetuity of the race, and "do far more to banish sickness from the cottage home" than all the serums and disinfectants in or out of the Pharmacopœia.

*Annual Report, 1900.

DUST DESTRUCTORS.

At the St. Bride Foundation Institute, Fleet-street, under the auspices of the Association of Parochial Engineers and Engineers-in-Charge, Mr. C. Newton Russell, A.M.I.C.E., recently gave an interesting lecture on "Dust Destructors." In the course of his lecture, which was illustrated with lantern views and diagrams, Mr. Russell remarked that the problem of disposing of towns' refuse has exercised the minds of those connected with municipal affairs for many years. The old system of shooting rubbish on vacant plots of land, which offers the easiest and cheapest way out of the difficulty, is doomed, as it is now generally recognised that in order to deal with the problem in a really satisfactory manner, the first requirement is that of sanitation. Burning refuse is a much more expensive way of dealing with it than shooting it on the land, but the hygienic benefit is of such incalculable value to the public health that the matter of cost should be of secondary importance.

The subject appears to have first been tackled seriously by Mr. Alfred Fryer, who more than twenty years ago was the first to do anything in a practical way; in fact, it may be safely said that the destructors of to-day are the result of that gentleman's foresight. To prove the old saying, "nothing new under the sun," Mr. Fryer quoted the tradition that the fires of Tophet received the burnable refuse of Jerusalem. In giving a detailed description of the Shoreditch destructor, the lecturer stated that the average amount of refuse received per day is 84 tons, delivered between 9 a.m. and 5 p.m., although occasionally as many as 140 tons have been delivered in one day. As it is impossible to guarantee a regular supply, storage is provided to cope with extra large deliveries by means of a large bin under the tipping platform, holding about 60 tons of refuse. The lifts and tip trucks are worked entirely by electricity, and are found to act well. The record time required to deal with each load of refuse shot into the lifts, raised to the top platform, tipped, and the empty truck returned to the starting point, in seven minutes, the average time being about nine minutes. Provision for the rapid shooting of garbage is important, as the vans usually arrive in batches.

In order to give an indication of the temperature reached in steam-raising destructor plants, Mr. Russell mentioned that he has selected a number of articles which have passed through the furnaces, from which it appears that such metals as cast steel, cast and wrought iron, copper, brass, &c., frequently reach a molten state. The highest temperature noted in this way is the fusing point of cast steel, viz., 2500 deg. Fah. The furnaces have now been in daily use for nearly four years, and it is interesting to find that the fire-bars are in good condition, and show very little sign of deterioration. The fire-brick linings of the furnaces are found to last well, and do not often require renewing. The boiler feed is furnished by a Weir pump, which forces the cold water through a Green's economiser, where it is heated to a temperature varying with the load. It is then forced into the thermal storage vessel—a cylindrical shell, 30ft. by 8ft.—from which the boilers are fed directly by gravity. Most of the lime deposit in the water comes down in this storage vessel, the amount taken out after a run of seven months weighing little short of a ton after it was dried. This system of feed storage has undoubtedly helped considerably to the success of the plant generally.

Another interesting point mentioned by Mr. Russell is that coal is never mixed with the refuse, but is burned separately on the ordinary grate immediately under the boiler tubes. The residue at present produced at Shoreditch represents about 33 per cent. of the amount of refuse burned. The clinker produced—which is rather softer than that produced at non-steam-raising destructors—and the fine ash are used for making mortar, concrete, and artificial paving stone. The stone consists of $2\frac{1}{2}$ parts ground clinker to one of Portland cement ground very fine and pressed to $1\frac{1}{2}$ tons on the square inch. A sample of slab when supported at its ends sustained a weight of 2221 lb. before breaking. The flue dust may be used as the basis of disinfecting powder, and is sold for a nominal sum per ton. In conclusion, Mr. Russell said he was strongly of opinion that to get the best efficiency out of refuse furnaces they should not be combined with coal fires, as when the steam from both sources is mixed in a common steam pipe it is difficult to allocate any carelessness. This point will be appreciated more when it is remembered that about ten tons of refuse has to be handled to get the same result as with one ton of coal, even when the latter is quite handy. Mr. Russell also gave the opinion that the extreme limit of percentage to which ordinary refuse can be reduced by burning is not near reached, the present lowest being 25 or 30 per cent. Having lately given considerable attention to this point, he was pleased to be able to say that it is quite possible to reduce the percentage of clinker down to 10 per cent., but as the new process was not fully developed, he was unable to give details.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

YORKSHIRE.

Members of the Yorkshire branch of the Incorporated Society of Medical Officers of Health had their annual dinner on Thursday evening last at the Hotel Metropole, Leeds, about fifty medical gentlemen from various parts of the county being present. Dr. W. L. Hunter, of Pudsey, presided. The invited guests included Dr. G. Vivian Poore (London), Mr. R. E. Bicknell of the Local Government Board, Dr. Peter MacGregor (Huddersfield), and several chairmen of Sanitary Committees in Yorks.

In proposing the toast of "The Public Health Service," Dr. Vivian Poore made special reference to the reports of Inspectors of the Local Government Board, expressing regret that these were not made more accessible to the general public.

Mr. R. E. Bicknell, M. Inst. C.E., briefly replied. Touching on the great housing question, he said that when Sanitary Authorities realised the very large powers they already possessed, progress would become general.

Dr. J. R. Kaye, hon. secretary, also responded.

Dr. J. Spottiswoode Cameron gave the toast of "The Sanitary Authorities of Yorkshire." Councillor E. E. Lawson, chairman of the Leeds Corporation Sanitary Committee, and Alderman J. E. Goodall, chairman of the Pudsey Sanitary Committee, replied.

"This Society" was submitted by Dr. Peter MacGregor, who urged that their great aim should be to educate not only the people, but the Sanitary Authorities, and even the Legislature, on health matters. He claimed that the serious attention of Medical Officers should be given to other diseases besides those which are strongly infectious or arise directly from insanitary conditions, and he specially instanced cancer and functional disease of the nervous system. Both these diseases, he remarked, were growing to an alarming extent in the West Riding.

Dr. T. A. Green, of Meltham, responded.

Earlier in the day, members of the Society had an opportunity of visiting and inspecting the Leeds sewage works at Knostrop.

The Corporation of Portsmouth has decided to borrow £90,000 for additional works of outfall drainage, and £32,000 for electric lighting works.

MECHANICAL AIDS TO DISINFECTION.

The science of disinfection has made rapid strides in recent years, and the introduction of formaldehyde has to some extent revolutionised its methods. Until recently, however, there were no mechanical appliances for the scientific distribution of this disinfectant on the market at reasonable figures. The Sanitas Company, Limited, of Bethnal Green, in order to meet the want, have introduced several distinct inventions, two of which are termed "Formic - Sulphugators," ingeniously contrived appliances which generate sulphurous acid gas (sulphur-dioxide) in conjunction with the vapours of Formaldehyde. As our readers are aware, carefully-conducted investigations have demonstrated the fact that disinfection with Formic-aldehyde vapour is but slightly superior to disinfection with sulphurous acid. By the use of "Formic-Sulphugators" the two methods are combined, and hence double security is assured. The heat generated by the burning sulphur is utilised to generate "Formic aldehyde" from a suitable (solid) combination, and both the sulphurous acid and "Formic-aldehyde" are generated in association with aqueous vapour in such manner that they are chemically compatible, and the full power of their several disinfective values is realised. These appliances retail at 1s. and 1s. 6d. respectively. The former (Fig. 1) consists of a double tin, the inner one (*b*) containing a sulphur candle, or fumigator, provided with a lighter (*c*), while in the outer one there is a preparation of Para-formaldehyde with other inert material. Before use, water—or a solution of Formaldehyde if preferred—is poured on to the top of the material in (*a*) until it is no longer soaked up. Upon lighting the sulphur candle, the heat which is generated thereby gradually causes the vaporisation of the disinfectant material contained in the vessel (*a*), and thus gives rise to a steady current of Formaldehyde vapour in association with steam and sulphurous acid. One such "Formic-Sulphugator" is sufficient to thoroughly disinfect any room of ordinary size (up to say 2000 cubic feet capacity), using water in (*a*). For larger apartments the water should be replaced by a solution of 40 per cent. Formaldehyde. Fig. 2 consists of three combined tins, the inner one (*a*) of which contains a preparation of Para-formaldehyde from which that substance is vaporised by the heat of the burning sulphur candle (*b*) provided with a lighter (*f*). The fumes of the Para-formaldehyde pass along and out from the tube (*d*) which is connected to the lid of cover (*e*). Into the outer vessel (*c*) water, or a solution of Formaldehyde, is poured, until the surface of it nearly reaches the level of the sulphur candle. In use, sulphurous acid gas is generated in association with the vapour of Para-formaldehyde and steam, while if a solution of Formaldehyde is placed in (*c*) instead of water, that disinfectant is also vaporised at the same time. It is not necessary, however, to use a solution of Formaldehyde in place of water except in cases where the room or apartment to be disinfected is larger than an ordinary room. For each extra 1000 cubic feet of space—above and beyond the cubical capacity of an ordinary room—there may be placed in the vessel (*c*), instead of water, a quarter pint of a 40 per cent. solution of Formaldehyde. Although but recently introduced, these "Formic-Sulphugators" have already met with unqualified

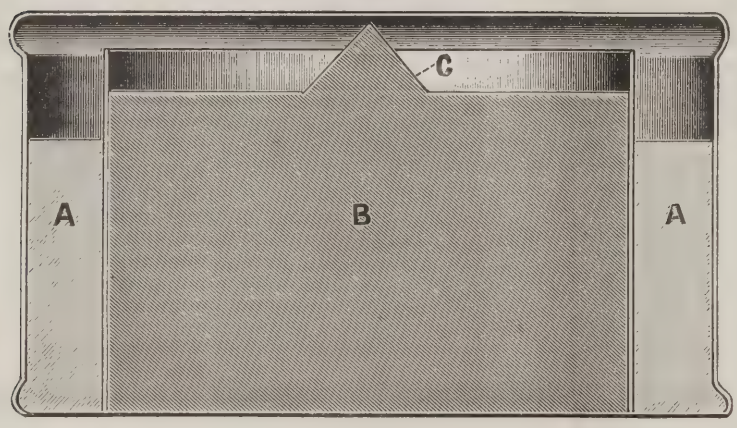


Fig. 1.

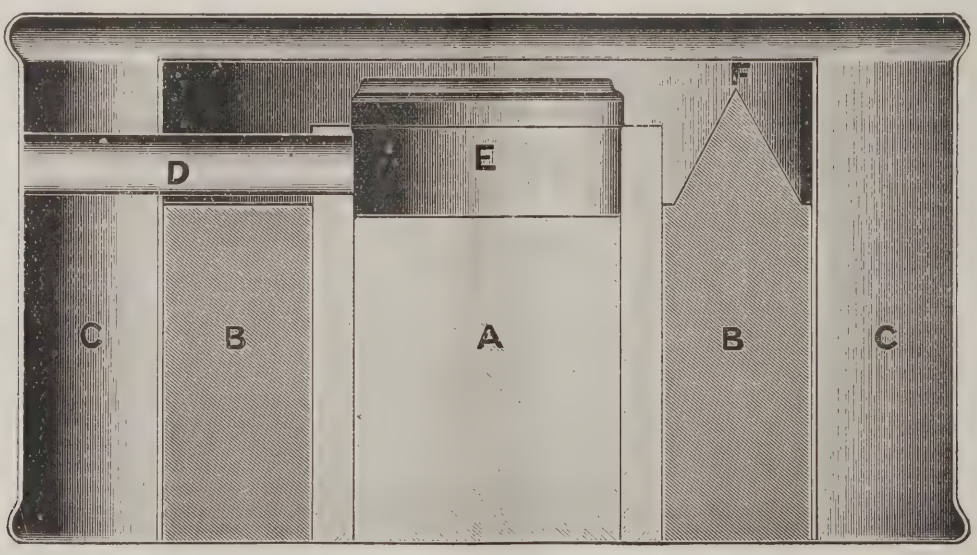

Fig. 2.

approval from a large number of Medical Officers of Health, and others interested in public disinfection, not only on account of their reliability, but their portability, safety, and, last, but by no means least, their economy. The apparatus though characterised by simplicity is nevertheless strikingly ingenious, and one can imagine no appliance better adapted for the use of Public Health Authorities, to whose attention we unhesitatingly commend it.

BOSTON RURAL DISTRICT COUNCIL AND ITS M.O.H.

EXTRAORDINARY ACTION.

At the last meeting of the Boston Rural District Council, Mr. F. E. Bowser presiding, the claim for 7s. 6d. by Dr. A. Tuxford, M.D., the Medical Officer, for notifying three cases of infectious disease at Hubbert's Bridge and Kirton Holme was further considered. At the previous meeting the Clerk reported that fees for the same three cases were also charged by Dr. White, of Swineshead, and the matter was adjourned for further consideration. Dr. Tuxford now wrote stating that he had communicated with the editor of the *Lancet* on the subject, and he was of opinion that he (Dr. Tuxford) was entitled to charge the fees, as he was called to visit the cases. If the Council, however, felt any diffidence about paying, he was willing to waive the claim. All he desired to do was to establish his right to make the claim, and this he considered he had done.

Mr. James Brown, the representative for Wyberton, moved that the amount be not paid. The Medical Officer, he said, was paid a stipulated salary for discharging his duties, and he had no right to charge extra fees.

Mr. Clarke seconded the proposition, and it was carried.

The Clerk, in reply to Mr. Maltby, said he was of opinion that Dr. Tuxford's was not a legal claim. Every medical practitioner attending a case of infectious disease was bound to make a notification, for which he was entitled to charge a fee, but that did not apply to the Medical Officer of Health, who visited the cases in his official capacity and by direction of the Sanitary Inspector.

The next business was to appoint a Medical Officer of Health.

Mr. J. Clarke proposed that the appointment be advertised, and said that he, like a good many more, was not satisfied with the present officer.

Mr. J. Brown seconded the motion, and in most eloquent terms severely criticised the action of Dr. Tuxford, and especially referred to his report.

Mr. Jas. Eley proposed that Dr. Tuxford be re-appointed, and contended that the Medical Officer had merely discharged his duty.

Canon Staffurth seconded the amendment. Dr. Tuxford's report might not be agreeable, but they could not deny its truthfulness. To dismiss him because his report did not please them savoured of Eastern customs rather than Western methods. If a doctor presented a report on the health of the Sultan which did not please his Excellency, he (the doctor) was handed over to the Eunuch and punished, and it seemed as though the Council wished to treat their Medical Officer in a similar manner.

Mr. Upsall supported the amendment. It would be frivolous to dismiss the Medical Officer in pique, and he did not think they would be able to give a very satisfactory answer to the Local Government Board.

On a division the proposition was carried by ten votes to nine, and it was decided to advertise, and to make the appointment on Saturday week.

National Health Society.

OFFICIAL TRANSACTIONS.

Elementary Examinations.—The following are short reports of examinations recently held in Bedfordshire and Lincolnshire, in both of which counties the Society's teachers have been engaged for some successive years:—

In *Bedfordshire* 107 candidates from five centres presented themselves for examinations in Nursing, First Aid, and Health. This is perhaps the largest number of candidates ever examined by the Society's examiners in one county during a week, which is in itself a testimony to the amount of interest taken in the teaching by the people in this county. The examiner speaks highly of the work of the candidates, and only nine out of the entire number failed to reach the required standard. The village of Silsoe is especially mentioned in the report; the examination in this centre was on "Health," which is usually regarded as less attractive and interesting than the other subjects dealt with by the Society's teachers, but the candidates in this case showed a keen appreciation of the instruction they had received, and all succeeded in passing the examination most satisfactorily.

Lincolnshire.—Fifty-six candidates presented themselves for examination in five centres in Lincolnshire on March 11th and following days, and of this number forty-seven have succeeded in obtaining the Society's elementary certificate for "Nursing," "First Aid," and "Health." The examiner speaks well of the high efficiency of the candidates, but mentions that those examined in "First Aid" attained a higher standard than candidates on either of the other subjects.

Training Lectures.—On Wednesday, March 27th, Mr. F. Stockman will commence his course of instruction on "Building Construction" for the Society's training students. These lectures will be given at three p.m. at 53, Berners-street.

The subject of Dr. Squire's lecture on Physiology on Tuesday next, April 2nd, will be "The Respiratory System."

THE ALLEGED INSANITARY CONDITION OF H.M.S. BRITANNIA.

Dr. J. W. Fisher, Medical Inspector-General of the Navy, and Professor Corfield, London University Hospital, the Admiralty Commissioners appointed to inspect the Britannia, are stated, on excellent authority, to have arrived at the conclusion, after a thorough investigation, that the ship should be retained, at all events for some time to come, and that although there are minor defects, which they recommend should be remedied at once, there is nothing in the sanitary condition of the ship to injuriously affect the health of the cadets. The present Britannia is not the ship originally stationed at Dartmouth, but took her place some twenty or more years ago. At that time she was a new vessel. Examinations by boring and in other ways convinced the experts that so far from being rotten, as was stated by one individual during the correspondence, she is practically sound. Alterations to the studies and sleeping berths are, it is understood, suggested, and in all probability, with certain other improvements, will be carried out without delay.

The following letter has been addressed to the editor of the *Times*, on the subject of the sanitary condition of Dartmouth by the Town Clerk (Mr. O. S. Bartlett) at the request of the Corporation:—

Dartmouth, March 14th, 1901

Sir,—I am directed by the Town Council of this borough to write you with reference to the corre-

spondence which has recently appeared in your columns as to the sanitary condition of Dartmouth.

Referring to the letter of your correspondent in answer to that of Mr. Councillor Ditcham, I am desired to state that the cases of infectious diseases therein referred to as notified within a period of a few weeks are cases of measles among children, measles and chicken-pox, which are not mentioned in the Infectious Diseases Notification Act, and which are not generally notifiable, being in this town notifiable diseases, Dartmouth in this respect occupying an almost unique position.

Epidemics of measles, as is well known, occur periodically, at intervals of a few years almost everywhere. The recent epidemic at Dartmouth was one of these, and the disease has been of a very mild type.

The schools were closed by the order of the Town Council as soon as the disease was found to be epidemic, and this course has been attended with very satisfactory results.

During the time the Britannia has been at Dartmouth, a period of thirty-seven years, there have only been (including deaths from drowning and as the result of accident) eleven deaths of cadets on the ship or in the hospital connected therewith, a number which will compare favourably with the number of deaths at any public school of the same size. I may mention that there are now over 280 cadets belonging to the ship, and not 235, as stated by your correspondent. In this connection, too, it should be borne in mind that while at public schools boys are generally sent home when ill, they are, when on board the Britannia, relegated to sick quarters.

The allegation that the tidal water drives the sewage back into the town is incorrect, as the mode in which the sewers are constructed renders this an absolute impossibility.

The statement that cases of eczema are common in Dartmouth is, as I am enabled to state on the authority of the Medical Officer of Health, absolutely without the slighest foundation in fact, and the Council can only regard the allegation that children are disfigured by it as made maliciously.

That the health of Dartmouth will compare favourably with that of any other town of its size in the kingdom is conclusively shown by its death-rate, the deaths during the past ten years having averaged only 99 per annum, being at the rate of 16·5 per 1000 of the estimated population.

The Council do not consider that it falls within their province to say anything with reference to the Britannia, but they are confident that everything is being done by the Admiralty that can possibly be done to ensure proper sanitary conditions on board that ship.

Onesimus S. Bartlett, Town Clerk.

It is stated that the report of the Board of Visitors appointed by the Secretary for War for the inspection of the Royal Military Academy, Woolwich, is favourable so far as the lads personally are concerned, but the Board considers that the barrack accommodation is not satisfactory, some cadets having single rooms, whereas others are placed three or four in rooms which are so small that no cubical arrangement is possible.

The new Birmingham typhoid fever hospital was opened last week, when the hospital at Little Bromwich became available for the reception of patients. Till recently the hospital had been used for convalescent cases of scarlet fever. The building has now been thoroughly cleansed and disinfected, and additional nurses have been appointed, an important provision under this head being the appointment of a night nurse. The hospital will accommodate 100 patients, though it is hoped the whole of this accommodation will not be required.

REVIEWS.

London County Council: The Housing Question in London. Being an Account of the Housing Work done by the Metropolitan Board of Works and the London County Council between the years 1855 *and* 1900, *with a Summary of the Acts of Parliament under which they have worked.* Prepared under the direction of C. J. Stewart, late Clerk of the Council. London: P. S. King and Son, Great Smith-street, S.W. 1900.

The Cottage Homes of England: The Case against the Housing System in Rural Districts. By W. Walter Crotch. Second edition. Price 2s. net. London: P. S. King and Son, Great Smith-street, S.W. 1901.

These two books deal with distinct phases of the "greatest social problem of the day." Mr. Stewart's report was published towards the close of last year, and will prove of immense value to all who desire to know what has really been done during the last fifty years to improve the artisans' dwellings of London. But it does more than give this information. The chapter on action taken by the Legislature gives in a concise form the chief features of all the Housing Acts, how they may be put in motion, and sets forth their weak and strong points. Aided by this summary, any one can obtain a really good idea of the extent of past legislation. Those responsible for the administration of affairs in districts other than the metropolis will see from the summary the sections applicable to their case, and may go at once to the fuller details in the particular Act they wish to adopt. Other chapters deal with the law on overcrowding and workmen's trains. The greater part of the book refers to works undertaken by the Metropolitan Board of Works and the London County Council. Full plans are given of every district dealt with. Mr. Stewart (who was assisted in compiling of the report by Messrs. W. J. Russell and M. H. Cox, LL.B. Lond.) has marshalled his facts with considerable skill. They are given in a way interesting to the general reader, but also sufficiently technical to be of real help to the administrative officers of Councils of all kinds. A number of valuable appendices are printed, which give the cost of various schemes, balance-sheets of dwellings erected by the County Council, and other useful information.

Mr. Crotch's book is of a more unpretentious character, but not the less valuable. It deals with the grave evils existing in rural districts, and urges the imperative necessity of a simpler procedure being adopted to cope with this complex question. We have no doubt that many of the uninitiated will be startled at the difficulties which beset the reformer at every point when he strives to get something better than a hovel for the farm labourer. Instead of Parliament helping, the whole aim of legislation seems to have been in the direction of "how not to do it." The account given by the author of various attempts made to put the Housing Act in motion is full of interest, but contains very little that will encourage others to try and grapple with the difficulty. Even when the preliminary conditions of the Housing Act have been complied with, there may be obstacles in the way of purchasing land, and this, as a last resource, has to be carried out under the Public Health Act of 1875. The following procedure will have to be gone through:—

(1) Advertisements and deposit of plan in November.
(2) Notices to and inquiries of all owners, lessees, reputed owners, &c., of land proposed to be taken.
(3) Petition by Council to Local Government Board, with detailed statements as to the land, &c., and such evidence as the Local Government Board may require.
(4) Local inquiry by Local Government Board.
(5) Notices of advertisements of proposed Order.

(6) Provisional Order by Local Government Board. (But this Order is of no force until it is confirmed by Act of Parliament. Sect. 297, 3.).

(7) If a petition is presented against the Bill, it may be referred to a Select Committee of the House of Commons, and the petitioner may appear and oppose as in the case of private Bills. Of course, again, the costs of an opposed petition are enormous, and it is very unusual to make a landowner opposing the taking of his land to pay.

(8) Ditto, ditto, in the House of Lords.

(9) Act of Parliament to confirm the Provisional Order of the Local Government Board.

By the time all this has been done, a pretty bill of costs will have accumulated, and the houses will be a dear luxury. The chapter on last year's Act adds considerably to the value of the book. It points out that the best feature of that Act is the one giving the Parish Council a court of appeal in the shape of the County Council. The book is well got up, and is worthy the attention of every true social reformer. It is well written, and free from the "padding" so often put into books of this description.

MUNICIPAL ENGINEERING & SURVEYING.

CROSS-TABLE CHAT.

Municipal and Sanitary Engineers will be interested in learning that a second edition of Colonel Moore's standard treatise on "Sanitary Engineering"—or, as it might perhaps be more fitly entitled, "Sanitary and Sewerage Engineering"—will be published on March 30th at the price of 32s. There is no book so reliable and so well up to date treating on sewage disposal in all its various and latest forms; of the design and construction of works of drainage and sewerage, of the disposal of house refuse, &c.; and hydraulic tables, formulæ, and memoranda, including an extensive series of tables of velocity and discharge of pipes and sewers as this, and I earnestly advise those who are practically engaged in sanitary and sewerage engineering to obtain the new edition for their library.

It is most infrequent to hear of a municipality which is enabled to obtain a good revenue from the sale of sewage sludge; but I am informed that the Corporation of the City of Glasgow are an exception to the rule. It is stated that chemically treated sludge (unpressed) is sold at 4s. and 5s. a ton, whilst pressed sludge is sold for as much as 20s. per ton. Glasgow "Bailies" are proverbially long-headed, and there was some surprise manifested by other journals as well as this when it was announced a short time ago that the Corporation were proposing to spend a large sum of money at their sewage outfall works for the chemical treatment of sewage. On the converse side it must be admitted that the farmers and others who buy the sludge at such fabulous prices are "puir bodies," who will sooner or later awaken to the fact that their estimate of the manurial value of the sludge is sadly out of proportion, and that as a matter of fact its monetary value is much less than that of an equal bulk of farm-yard manure. Most Local Authorities have found to their concern that whilst a demand for a period existed for pressed and dried sludge at a fair price, such demand ceased to exist altogether, and finally they were unable to dispose of it even as a free gift. I venture to predict that the Glasgow Corporation will be rudely awakened before long to the fact that their adherence to the "ancient" system of chemical precipitation and sludge manufacturing has led them into a useless and excessive waste of capital.

I venture to think that there are few engineers who have devoted more attention to the "Details of Drainage Construction" than Mr. Gerard J. G. Jensen, who recently read an excellent paper on the subject before the Society of Engineers, a report of which has appeared in our pages. Mr. Jensen is the author of "Modern Drainage Inspection and Sanitary Surveys," price 2s. 6d., and of "House Drainage and Sanitary Fitments," price 5s.—books which are in very considerable demand, and give the results of the experience of an engineer who is not only theoretically sound, but is also thoroughly practical; and I refer to his recent paper in this column in order that other engineers may have their attention more particularly directed to the important lessons which can be gained by a careful perusal of it.

Mr. Jensen suggests that in the construction of ventilation pipes to drains to avoid the loss of action due to bends, that the diameter of the pipes should be increased at the bend—a suggestion which appears to be entirely original. His experience with ventilating cowls is that such are of no practical value, and that a copper-wire guard for the terminal end of soil or ventilation pipes cannot be excelled.

The instance which was cited of cases of follicular tonsilitis—a disease always suggestive of defective drainage—periodically occurring in a large school, where the ventilation shafts in connection with the house drains terminated in close proximity to, and on a level with, dormitory windows, is one which is, unfortunately, all too common; and engineers and others who have to design or superintend the construction of drainage should insist on the outlets of such shafts being carried as far away from bedroom windows as possible.

Although there are, I know, some engineers who advocate, without reasonable grounds, the abolition of disconnecting traps, the illustration given in the discussion which followed of an epidemic of tonsilitis occurring in a large institution comprising numerous isolated blocks connected to the sewer by one main drain on which one disconnecting trap only was constructed, and all the drains freely ventilated, should be a warning as to the danger which is attendant upon their pushing their idea too far. It had been observed that in another similar institution with ward blocks arranged similarly to the former, but where the drainage of each block was disconnected from the rest by an intercepting chamber, no such disease manifested itself. The engineer, after full consideration, provided intercepting chambers to disconnect each block wherein disease had periodically occurred from the rest, and, as a result, its occurrence ceased.

I would draw the attention of my readers who are interested in the subject of model or industrial dwellings to an admirable paper on "Rowton Houses" by Mr. H. B. Measures, which was read before the Architectural Association on the 15th inst. The design and general execution of the work of these buildings is as nearly perfect as is humanly possible, and the author described these, and also the details of management in such a manner as cannot fail to be of especial interest to municipal engineers and sanitary officials, who will derive much benefit from a study of the paper. Senex.

At a meeting held in the Horniman Hall, Croydon, a resolution has been unanimously carried, appealing to Mr. Ritchie to use his influence to securing the full statutory period of sixty years for the repayment of building loans in connection with housing schemes undertaken by Local Authorities outside London, and to enable Local Authorities to borrow money at the standard rate of interest (2½ per cent.) from the Public Works Loan Commissioners for housing schemes.

NOTICES.

ANNUAL SUBSCRIPTIONS.—The Annual Subscription to "THE SANITARY RECORD," for the United Kingdom, paid in advance, is 12s. 6d. For the Colonies and Abroad, 15s This includes postage, and a Copy of the Diary, post free.

MSS. cannot be returned unless accompanied by a stamped directed envelope.

SUBSCRIBERS RESIDING IN SCOTLAND AND IRELAND are requested to pay by P.O. and *not* by cheque. If cheques *are* sent they must be drawn for 13s.

ALL applications for advertising spaces from firms in the United States should be addressed to THE TRADE PAPER ADVERTISING AGENCY, American Tract Society Building, 50, Nassau-street, New York, our sole representatives, who will furnish tariff rates and all particulars.

ADVERTISEMENTS cannot be inserted unless received by first post on WEDNESDAY morning.

ALL Communications should be addressed to the EDITOR, at 5, FETTER LANE, LONDON, E.C., and Cheques and Postal Orders should be made payable to THE SANITARY PUBLISHING COMPANY, LIMITED.

PORT SANITATION.

SOME explanation of the comparative immunity of this country from plague and other contagious diseases of a deadly type is afforded by the annual reports of the various Medical Officers of the Port Sanitary Authorities, the most important of which have recently reached us. It reflects great credit upon the Port Sanitary Authority of the Port of London, and upon Dr. Collingridge's splendid administration, that the metropolis enjoyed during the whole of last year a remarkable immunity from contagion; but London does not stand alone in this respect. Special praise is due to the big sister Port of Liverpool, where Dr. E. W. Hope and his staff took precautions that deserve widespread publicity as being typical of what capacity and energy combined can effect on an emergency. Incidentally, the Liverpool Port Sanitary Authority is to be congratulated on the fact that its operations are greatly facilitated by the Mersey Docks and Harbour Board, which is fully alive to the exigencies of the situation. An arrangement is consequently in operation that no vessel coming from an infected port is allowed to enter a dock until she has been boarded by the Medical Officer of the Port Sanitary Authority and the captain has received a certificate from that officer. The active precautions against the incursion of plague merits special notice. Last year plague was diffused in a remarkable manner. Following the lines of seaborne commerce, it made its appearance in seaports thousands of miles apart, appearing in places so remote as Hong Kong, Bombay, Buenos Ayres, Sydney, and San Francisco. Under these circumstances, as Dr. Hope points out, it is no matter for surprise that cases should have been brought to the shores of this country, which possesses the largest mercantile marine in the world. Not only Liverpool, but London, Newcastle, Cardiff, King's Lynn, and Glasgow had isolated cases of disease brought to their ports, which there is no reason to doubt were cases of plague or convalescence from that disease. In Glasgow, despite its excellent sanitary equipment, the disease unfortunately found a foothold, and this, of course, necessitated a large addition to the port staff of Liverpool, so that the numerous vessels coming from Glasgow could be medically overhauled. To cope with this danger the staff of Inspectors was increased by seventeen, additional medical assistance was obtained, and the services of Dr. Balfour Stewart, an expert on plague, were secured. War was declared against rats; in fact, nothing was left undone that human ingenuity could devise to keep the dread disease at bay. From a public health point of view the circumstances attending these and similar precautions, and the successful manner in which the whole of the Port Authorities of the kingdom, without exception, rose to the occasion, should serve to reassure any whose minds are timorous in regard to contagion. The gratifying fact remains that the sanitary administration of the seaports was adequate to promptly suppress a form of disease, the appearance of which has always been associated in the public imagination with devastating consequences. This experience further serves to confirm the view that the appearance of plague in a seaport in this country must derive more importance from the commercial losses which it will entail, owing to foreign quarantine, than from any material influence which it is likely to have upon the public health, so long as rigorous measures are directed against it. No less energetic than the precautions against plague were those against small-pox, which was introduced on

eight occasions. The measures taken were somewhat drastic. For example, on the 30th of March the steamer New England arrived in the port flying the yellow flag, and was detained in the river until every person on board was re-vaccinated and disinfecting measures taken. Two lighters were interposed between the ship and the quay, so as to prevent communication except by the gangway. The quay was barricaded opposite the vessel. The shed opposite the vessel was cleared, closed, and all doors except one locked, and that one was watched by a person told off for the purpose, with orders to allow no one except the sanitary staff to pass, until the patients and their effects were removed. After the removal of the patients, access to the shed was allowed to the officers of the steamship company. Nineteen cases of small-pox and six suspected cases were removed to the hospital; and five attendants were removed for the purpose of vaccination and disinfection. All the other members of the crew and passengers were bathed, and changed into clothing which they alleged had not been used previously during the voyage. All articles of clothing, bedding, linen, curtains, cushions, &c., which had been in use during the voyage were removed from the vessel and disinfected by steam. The remainder were sulphured for twenty-four hours in the various compartments of the vessel. The disinfection of the articles taken away occupied five days.

From the foregoing, which we give as a typical instance, it will be seen the Port Sanitary Authorities of Great Britain can vie admirably with their inland brethren when there is hard work to be done. What Liverpool did was done, with modification, of course, in every instance. And the result we all know. In our opinion too little credit, by comparison, is given to this Department of Sanitary Administration. Be that as it may, one thing is certain—our Port Sanitary Authorities do their duty, and do it admirably.

Dr. Sykes at the Statistical Society.

Last week the well-known Medical Officer of Health of St. Pancras gave a most valuable paper on the housing question before the Royal Statistical Society. Dr. Sykes has spent a vast amount of time in obtaining the fullest information on what has been done, not only by the State, but by municipal and private means, to secure better houses for the working classes, and the paper gave the result of his extensive investigations. In summing up, he gave it as his opinion that in the hands of Municipal Authorities flats and blocks did not appear to pay so well as cottages, but in the hands of private companies they appeared to pay moderately. There was ample scope for individuals, private associations, and public bodies; and competition among them was benefical, provided it was upon a proper financial basis, and that bye-laws and regulations controlled all equally. Public Authorities must always be somewhat handicapped in competition on account of the publicity and routine involved in their transactions; on the other hand, they had the opportunity of evolving the best types of dwelling as standards of encouragement to private undertakings. If it could be made to pay, private enterprise would take the field; if not, not only would it be forsaken by individuals, but opinion would also prevent the action of Public Authorities, and an opening would hardly be left even for philanthropic efforts, since true philanthropy now-a-days had a financial basis for guidance. In the concluding portion of his paper, Dr. Sykes discussed the conditions that should govern future action. The remedy applied for overcrowded areas was clearance and reconstruction, but, owing to modern bye-laws and standards of building, fewer persons could be housed on the sites. Disappointment that the class displaced did not enter the new dwellings was only expressed by those unfamiliar with the movement of population produced by the clearance of an unhealthy area, but the mingling of the better with the worse thus caused must produce good educational effects since the worst houses were destroyed. How to deal with those who were determined, rather than were driven, to bury themselves in dark and unsalubrious places was more a social than a sanitary question, and depended more on education and supervision than on construction. Houses in a pressure zone were sub-divided more and more into smaller and smaller dwellings, and it was at this stage that arose the most serious point in the housing question—a point which had commanded very little of the attention it deserved. Some provision was urgently required to assist and stimulate both private and public owners to adapt houses to the requirements of separate dwellings. Mr. Cadbury's scheme, to which we directed attention last week, will do much to stimulate the building of such dwellings. The block system can only be defended under the most exceptional circumstances; and with the new powers given by last year's Act, it will be better to build cottages outside than these hideous structures inside our towns and cities.

An Indian Memorial.

In all parts of the British Empire proposals are being considered for the establishment of permanent memorials to the late beloved Queen. In most cases monuments or other combinations of masonry are proposed, but here and there the ideas take a wider scope, and schemes of usefulness have been suggested. One of the best of these comes from India, and takes the shape of a "model city," which shall possess every advantage for the promotion of health that modern sanitary science can provide. As we have said, the idea is a good one, but the means suggested by the originator for carrying it out are open to objection. He suggests "Victoria City" as the name, and goes on to propose that "the people might be located by selection in the city according to the lists furnished by all the subscribers of those they think the most worthy amongst the inhabitants of India. The city should be placed in some central district where there is a lot of culturable waste land, and

arrangements would be made for the allotment of this land, irrigated out of the general fund, at a fair rent to the inhabitants of the city, by lottery, and in such parcels as would be considered best for the general welfare of the people. Good roads, wells, and outlet drainage on the land would form part of the initial scheme. Given these, Victoria City would at once jump into prominence as one of the leading cities of India." India, we admit, greatly needs reform in the condition of many of its cities, but it had better wait than have them re-modelled by the aid of lotteries. The remedy is worse than the disease, and we sincerely hope that no memorial to Queen Victoria will be raised by such immoral and degrading means as here suggested.

Kimberley's New Medical Officer.

The diamond city of South Africa is to be congratulated upon securing so good a man as Medical Officer as Dr. Monk, who has just been appointed to the post. Although he has only been in Leicester about six years, he has proved a worthy successor of Dr. Priestley, who left Leicester for Lambeth. Perhaps there is no more difficult town in the country to administer than the centre of the shoe-making industry. It is the seat of a sturdy, independent people, who possess strong feelings and prejudices, more particularly upon the question of vaccination, and for any man to succeed amid such surroundings, stamps him as being possessed of much common sense and tact in dealing with difficult cases. We understand that Dr. Monk has for some time had very indifferent health, which fact was one of the reasons prompting his application for the post. Commenting on his removal from Leicester, a local paper expresses its regret at the loss the borough will sustain through his departure. That during the five years he has served the town as medical chief and adviser, "he has throughout discharged his duties with efficiency and energy all will agree. If, however, there is one great public improvement rather than another with which his name and fame must be associated, it is clearly the completion of the Isolation Hospital at Gilroes. It must be some satisfaction to the retiring officer that he has been enabled to remain long enough in Leicester to see this erected and opened. It need hardly be added that he will be followed to Kimberley by the best wishes for his health and progress in his professional career."

Progress at Stockton.

The enterprising Corporation of Stockton last week completed another instalment of its effort to make the borough one of the most progressive in the country. The old system of refuse disposal is to be abolished, and a Horsfall destructor has been erected at a cost of £3091. Under the old system some 17,300 tons were collected yearly. This was disposed of to farmers and others. In addition more than 1300 loads of trade refuse were collected. Night soil also had to be dealt with, and the difficulties of disposing of so much refuse have increased annually. After considerable consideration the Corporation has come to the conclusion that better means must be adopted, and the erection of a destructor will obviate a vast amount of labour. The plan to be adopted is based largely on the practice at Bradford, where the quantity of clinker and ash produced amounts to about 30 per cent. of the material treated. Our readers will recollect that at Bradford the whole of this percentage of ash and clinker is utilised, none having been taken to the tips for about four or five years. From 100 to 150 tons are used per week (or, say, two-thirds of the whole) for the manufacture of mortar, which finds a ready sale. What is not sold is passed through a breaking and grading machine and sold to contractors and others at 8d. per ton—lifted and removed by the purchaser. A substantial revenue of about £1000 a year is obtained from these sales. Stockton hopes to succeed in a proportionate manner, as well as effect a great saving in the cost of team and manual labour.

The Employment of School Children.

Public attention is being increasingly directed to the excessive employment of children of school age, to the detriment both of their health and of their education. The Home Secretary, in consultation with the Vice-President of the Board of Education, recently appointed a Committee, under the chairmanship of Mr. H. H. S. Cunynghame, C.B., to inquire into the whole subject, and to report what alterations are desirable in the laws relating to child labour and school attendance, and in the administration of those laws. The question has also been engaging the earnest attention of many School Boards and similar bodies. The School Board of Glasgow, for example, has received returns from the headmasters, which show that nearly 6 per cent. of the children attending school are employed for wages, and about half the number thus employed, or 2300, are under thirteen years of age, and in the lower standards. Nearly half the children thus employed are engaged in the delivery of milk and a considerable proportion are engaged in the delivery and sale of newspapers. The hours of employment vary considerably—from under ten hours a week of five days to between forty and forty-five hours a week. The average period of employment is about three hours a day, only a small proportion being employed for more than five hours a day. According to another set of returns procured by the Scottish Council for Women's Trades, covering 1592 school children in Edinburgh, it appears that 242 of them work for more than thirty hours per week, and a certain proportion forty-eight hours. One case was reported of a child of eleven working forty-nine hours a week, and another in which a boy of fourteen was employed from seven in the morning till midnight on Saturdays. These ascertained facts are probably but a gleaning on the surface of the state of things that must prevail all over the country. They indicate too plainly that the day of child slavery is not gone. It must, of

course, be admitted that it is a delicate matter to interfere with the parental control of a child—there is no province in which it is more difficult for the State to intervene—but Britain has a right to demand that the children who will one day be her citizens shall have a fair opportunity of full development without being cramped and starved n the springtime of life. Educational Authorities naturally look at the question from their own standpoint. They find that children who come to school weary with previous work are in no fit state to receive instruction. Our standpoint is the effect which this excessive employment, over and above the hours they spend in school, must have on the children's health and their physical development. A little time spent in the delivery of milk or such occupations may not only be not injurious, but even beneficial; but it is the *excessive* employment which we have a right to object to, and the undue strain placed upon the tender nature of a child, which is certain to impede its future development.

Meat Inspection in Glasgow.

Some months ago the question of the inspection of meat was raised in the Town Council of Glasgow by a complaint from a local firm of pork butchers and pig dealers, that, while swine purchased by them were, after slaughter in Moore-street Market, examined by the Inspector appointed by the Local Authority before being passed for sale, a large number of pigs belonging to other owners were slaughtered in private shambles in Ireland and elsewhere, which were not subject to inspection, and the carcases of which were distributed throughout the city without any examination. The matter was remitted to a Sub-committee, who have since reported, and the Committee on Health, by a large majority, now recommend that for the greater security of public health, and in addition to the detective system of meat inspections at present in operation in the city, the Corporation, in virtue of the powers conferred on them by Section 33 of the Glasgow Police (Amendment) Act, 1890, should make bye-laws for the inspection of carcases, meat, and flesh brought into the city, and for the treatment and disposal of such as are unsound, and that it be remitted (1) to the Sub-committee to frame such bye-laws for submission to the Corporation for adoption, and thereafter to the Secretary for Scotland for confirmation; and (2) to the Committee on Health to consider and report on providing suitable and convenient premises for such inspection.

The Small-pox Epidemic.

It is hard to carry conviction to the mind of anti-vaccinationists. Of all sceptics they seem to be the most difficult to teach. During the present epidemic of small-pox in Glasgow the health department have been most urgent in insisting that vaccination was the only sure safeguard, and in his last fortnightly report to the Town Council, Dr. Chalmers, the Medical Officer of Health, laid special emphasis on the point, for the benefit of those who are still doubtful. "In view of the efforts," he says, "which are being made to discountenance the value of re-vaccination, there is a present importance in the statement that no case of the disease has been admitted to hospital, and no person is known to the department to have sickened thereof, in whom re-vaccination has been performed before the disease was contracted. It is equally true that the performance of re-vaccination does not increase the severity of an attack in those who have contracted the disease before the operation, but whose sickness only begins within the next few days after its performance. On the contrary, it greatly modifies the attack." Even this emphatic and authoritative testimony was not, however, allowed to pass without question in the Town Council. One member disputed its value, and cited a case which, he held, disproved the generalisation. The Lord Provost, in reply, said that he was most thankful that Dr. Chalmers had made this statement. It was most important that it should be known that no one had required to be admitted to hospital who had been re-vaccinated for a longer period than fourteen days. In the case which had been instanced, the patient had been re-vaccinated only eight days before removal to hospital, which showed that he must have contracted the disease before re-vaccination.

Caretaking in Tenement Houses.

Another matter of considerable interest came up at the same meeting of the Town Council to which we have just referred, in connection with the "minutes" of the Health Committee. This was an amendment moved by Bailie Stevenson, "That with a view to compel the proper caretaking of tenement houses, without which the tenement system is incomplete, the Corporation be recommended to apply for parliamentary powers to transfer the responsibility for the keeping clean of closes, common stairs, and lobbies from the tenants to the landlords." Every student of Scottish history knew, he said, that we imported the tenement system from France, but in doing so we neglected to bring with it the caretaker. He instanced the work of Miss Octavia Hill in London, of the Edinburgh Social Union, and of the Glasgow Workmen's Dwellings Company, as showing how, with proper caretaking, slum properties could be kept cleanly. It is largely a question of administration. After discussion, a suggestion that that question be remitted to the Health Committee for consideration was accepted, and became the finding of the Corporation.

A Board of Trade inquiry was held at Horsham last Thursday in reference to the application for a Provisional Order on the part of the Horsham Gas Company. In making the application, the Hon. A. Lyttelton explained that it was one for a Provisional Order conferring further powers upon the Gas Company, with the object of maintaining and continuing several additional gasworks. It was, he said, really a Provisional Order for the authorisation of works rather than the acquisition of land.

TUBERCULOSIS—INFECTION, HEREDITY, PREVENTION, HYGIENIC TREATMENT.

By A. G. Young, M.D., Secretary State Board of Health, Maine, U.S.A.[1]

(*Concluded from page* 228).

Is the breath of the consumptive infectious?—Cornet in 1888, and, before him, various investigators, were apparently fully justified in their conclusion that the breath of the consumptive patient is free from infection. That was accepted as an established truth until the year 1897, when Professor Flügge[28] asserted that the most frequent media of infection are particles, or minute vesicles, of fresh sputum thrown into the air during the act of coughing.

He also declared that the opinion that the principal agent in the transmission of consumption is dried and pulverised tuberculous sputum does not rest upon experimental investigation which is not open to criticism. It has not really been shown, he says, that the inhalation of dried sputum by healthy persons can produce tuberculosis.

One of the pupils of Flügge, Dr. Laschtschenko, found that in experiments with fluid cultures of bacillus prodigiosus held in the mouth, this germ was diffused in the surrounding air considerable distances.

Neisser[29] and others, in subjecting animals to the inhalation of dried tuberculous sputum, have had many negative results, due apparently to the fact that their methods were faulty in differing widely from the usual conditions present in the accidental infection of human beings.

Sticher,[30] on the other hand, succeeded almost without exception in giving animals tuberculosis by rubbing perfectly dry tuberculous sputum upon a piece of cloth or board, and blowing it into the room where the animals were confined.

A year and a-half after the publication of his first paper Flügge[31] admitted that the infection of pulverised tuberculous sputum succeeds if certain conditions are observed. But he criticises the successful experiments as deviating too much from the conditions in dwelling-houses, where so strong currents of air are not present to send the dried sputum into the air, forgetting, apparently, the efficiency of certain prevailing household methods of raising a dust, particularly dry sweeping and dusting.

Heymann,[32] another pupil of Flügge, experimented with thirty-five consumptive patients by having them cough in the direction of glass slides. Tubercle bacilli were found on the slides placed before fourteen of these patients, 40 per cent. of them, at a distance of half a metre (nearly twenty inches).

Engelmann made similar experiments with eight patients, and found that tubercle bacilli were projected to a distance of one metre.

After the publication of Flügge's first paper on this subject, Dr. Wissemann[33] criticised it rather severely, and suggested as a crucial test the suspending of guinea pigs in cages near consumptive patients.

Heymann adopted the suggestion with precautions against the infection of the animals from infectious dust or otherwise than with the particles of sputum, sprayed from the patient's mouth in coughing. From six to ten animals were used at a time suspended in cages so constructed that the heads of the animals were constantly directed toward the coughing patient. The distance between the mouth of the coughing person and the animals' heads was only from twenty to forty-five centimetres (eight to eighteen inches). The animals were coughed at three hours every other day by "suitably chosen patients" (expert coughers probably) and the ordeal of each animal was extended from several weeks to several months. The result was that of twenty-five animals which had not succumbed to other causes, six showed symptoms of inhalation tuberculosis, but Flügge, referring to the results, remarks that the exceedingly slow course of the disease in these animals was surprising; and further he says that, in some of the animals, nothing was found but partially caseous bronchial glands, and that it was impossible to find the bacillus of tuberculosis in many of these glands. We may safely assume, therefore, that the dose of infection received by these animals was exceedingly small, in spite of their long and intimate exposure. Flügge thinks that there is, therefore, sufficient proof of the infectious capability of the particles of fresh sputum sprayed from the consumptive's mouth in the act of coughing.

Experiments made by Cornet[34] show that, in the act of coughing, the bacillus of tuberculosis is strewn only by patients in an advanced stage of consumption whose expectoration contains an abundance of bacilli, and who have a hard explosive cough. But it is only a minority of these patients who thus scatter infectious particles of sputum.

Dr. J. J. Curry,[35] of Boston, made some experiments with twelve consumptive patients in accordance with the suggestions of Flügge for further investigations. He found a comparatively small number of bacilli in the mouth fluid, but a much larger number in the larger drops of the sputum which came from the trachea in open-mouth, hard coughing. In experiments with glass plates suspended from one to three feet before the mouths of the patients, one-half of the patients gave negative results. "It is worthy of note that *all* these cases had a low cough and kept the lips closed during coughing. Of the others, six positive cases, every one had a loud cough and kept the mouth open while coughing."

To decide the question anew which Flügge had raised, Cornet instituted an experiment which should be as nearly as possible like those conditions under which infection is all the time going on in the houses of uncleanly consumptives who spit upon the floor. The sputum of a patient in an advanced stage of pulmonary tuberculosis was thrown upon the carpet of a good sized room. It was left to dry two days. Guinea pigs were placed in the room, some on the floor and others at various heights in the room. Then with a coarse broom the carpet was swept so as to put the infectious dust in motion. Of forty-eight animals thus treated, forty-six were infected.[36]

Dr Hermann Koeniger[37] has just published the results of his experiments at the Hygienic Institute of the University of Halle. They indicate that in ordinary breathing, no germs are thrown into the air, but that in loud speaking and in coughing they are. The enunciation of the vowels gave negative results, and the number of bacteria projected into the air depends upon the sharpness with which the consonants are uttered. In forceful speech or in coughing, the germs reach all parts of the room, laterally and at the rear of the speaker as well as in front of him; but the time during which they remained suspended in the air was surprisingly short, much shorter than was indicated by the experiments of Flügge. In ten minutes there was a diminution in the

number of germs in the still air of rooms, and in one hour their complete absence was verified by many of the experiments.

SHIPLEY SEWAGE WORKS.

THE Shipley District Council, after four years of anxious labour, were last week able to put into full operation their extensive and important sewage works. There was a large attendance of representatives of various Authorities at the formal opening ceremony.

Mr. DUNN, who acted as chairman, said that that day was one of the most important days in the history of the Shipley Local Authority. The works that they were about to open formed the greatest undertaking that had ever been carried out in Shipley. They had expected to complete the scheme in two years, but it had taken them four. The Sanitary Committee had thought it only right that the chairman of the Council, who had taken great interest in the work, should have the honour of starting the pumps, and he would ask Mr. Paterson to present to Mr. Shaw a key with which to open the pump-house.

Mr. Paterson then presented to Mr. Shaw a gold key on behalf of the architects. The key was suitably inscribed, and was altogether a very handsome memento of an interesting occasion.

Mr. SHAW expressed his thanks for the beautiful present. He was very pleased, he said, to have the honour of opening the works. He recalled the fact that eight or nine years ago the Local Board had great difficulty in choosing a system. They were recommended to adopt the precipitation system; but after inspecting a variety of methods at different places, they resolved upon the bacteriological system. In their search for a site they went to view land at Esholt, but found there was not sufficient fall from some parts; but eventually they decided upon the 34½ acres at Dockfield. The works would cost them altogether something like £75,000. The destructor works had cost them also £4000. Mr. Shaw concluded by saying he was delighted to see so many visitors present.

Mr. Shaw then unlocked the door of the pump-house and set the pumps in motion. The gentlemen present afterwards inspected the various works; the destructor, which was in full working order; the bacteria beds, into which the sewage was flowing freely; and the engine houses. In 1893 the Shipley Local Board, as it then was, accepted the preliminary scheme of Mr. Malcolm Paterson for the works of sewage interception and treatment, and appointed him their engineer for the carrying out of the works. In September, 1894, the contract plans were adopted, to the total amount of £55,000. Owing to unusual pressure at the Local Government Office, and correspondence relating to the area of land to be devoted to the filtration of the tank effluent, sanction was not obtained until early in 1897, the first contracts being let in August of that year, for the whole of the intercepting sewers. Nine-tenths of the total flow of sewage is discharged into a storage tank sewer 8½ft. in diameter, and 792ft. long, holding 275,000 gallons, whence it is pumped about 47ft. into eight precipitating tanks, holding an aggregate volume of 1,000,000 gallons. Chemical treatment by lime and ferric-sulphate was at first proposed, as it was thought that trade effluents, including wool-washing and dye refuse, would be taken into the sewers, after preliminary treatment by the mill-owners. The tank effluent was then to be filtered through twelve acres of land. In 1898, however, the attention of the Council was drawn to the bacterial method of treating sewage, and ultimately they decided to put down bacterial filters to treat a dry-weather flow of 800,000 gallons per twenty-four hours, trade effluents being kept out. The series of "coarse" tanks have a bottom fall of 6in., and are filled to a mean depth of 3¼ft. with coarse clinkers. The fine tanks are filled to a like depth with the same material crushed and sifted. Thus taking the net working capacity in sewage volume as one-third of that of the empty filter, the capacity of each "fine" filter is 58,437 gallons, or a total of 233,748 gallons, and being filled three times daily the total volume which can be dealt with daily is 701,244 gallons. A supply conduit, 4ft. by 18in., extends along the head of the tier of tanks, and sewage is admitted to and discharged from each tank by four sluices. The effluent conduit extends along the foot of the tanks, and conveys the tank effluent to the land filter, wich will be about twelve acres in area, partly laid out on the pane and gutter system, and partly on the catchwater system. After filtration through the land the purified effluent is gathered into an open drain, with ledges 6in. wide, and samples can be taken to prove the efficiency or otherwise of every part of every bed, and also the discharging efficiency of each subsoil drain. The effluent drain discharges into the river Aire, which at this point is black and fœtid. To relieve the tanks and the land in time of heavy rain a storm-water conduit will take the sewage, after a dilution of two to one, from the settling tanks to a special filter of engine ashes, 2ft. thick, three acres in extent, with 4in. subsoil tile drains and 6in. seconds fire-clay pipes for drainage. The principle of discharging every drain into an open conduit is here also observed. The levelling of the three acres for the storm-water filter required the excavation of nearly 10,000 cubic yards of earth. The works are nearly finished, and it is believed that they constitute the largest installation of the bacterial system yet constructed in this country, and the Council express the hope that they will be able to demonstrate that this method of treatment can be adapted to the requirements of any community, however large, whose sewage is not sterilised by the admission of injurious trade effluents. The destructor, which is of large capacity, and has been in operation for several months, was constructed by Messrs. Meldrum Brothers, of Manchester.

Dinner was served in the evening at the Star and Garter Hotel, about fifty gentlemen being present.

FORTHCOMING MEETINGS.

MARCH.

Friday 29th.—The Sanitary Institute.—Lecture to Sanitary Officers at 7 p.m. Signs of Health and Disease in Animals destined for Food, when Alive and after Slaughter; Tuberculin and other Tests, by W. Hunting, F.R.C.V.S.

Friday 29th and Saturday 30th.—The Sanitary Institute.—Examination for Inspectors of Meat and other Foods, Birmingham.

Saturday 30th.—The Sanitary Institute.—Inspection and Demonstration at London County Council Sewage Disposal Works, Barking, at 3 p.m., conducted by Jno. Ed. Worth, M. Inst. C.E., District Engineer.

APRIL.

Monday 1st.—The Sanitary Institute.—Lecture to Sanitary Officers at 7 p.m. The Names and Situations of the Organs of the Body in Animals, by W. Hunting, F.R.C.V.S.

Wednesday 3rd.—The Sanitary Institute.—Lecture to Sanitary Officers at 7 p.m. Practical Methods of Stalling and Slaughtering Animals, by W. Hunting, F.R.C.V.S.

Thursday 4th.—Civil and Mechanical Engineers' Society.—Mr. A. Hanssen on "On the Proportions of Cylinders for Multiple-Expansion Engines." 8 p.m.

THE Madras Municipality derives a revenue of over Rs. 12,000 a year from its sewage farms, which comprise 58 acres.

Public Works.

SEWERAGE.

The Swansea Water and Sewers Committee has decided, with regard to the proposed sewage outlet at Brynhill, that the outlet near Vivian's stream be adopted. The estimated cost is about £60,000.

The Local Government Board has approved of the issue of a provisional order for the erection of sewage-disposal works at Drighlington, but has withheld its sanction to the application to borrow £12,660 for that purpose.

The Local Government Board has written the Lynton Town Council that the Board of Trade had sanctioned the scheme for extending the sewer outfall at Lynmouth as prepared by Mr. Chowins (Surveyor), and sanction for borrowing the necessary money has been given.

The Norwich Town Council has adopted the recommendations of the Sewerage and Irrigation Committee that the main sewage sewer on Dereham-road be extended from Bowthorpe-road to the junction of a new road with Dereham-road near the Lord Nelson public house, at an estimated cost of £70, that the main sewage and surface water sewers be constructed in Aylsham-road for the purpose of draining new building estates thereon from St. Augustine's Gates to the Windmill public-house, Aylsham-road, by men in the direct employ of the Corporation, at an estimated cost of £2867 12s. sewage sewer on Chapel Field-road to be extended into Coburg-street to drain Hudson's-buildings, at an estimated cost of £65, and that payment be made to Messrs. Sabberton Bros. of £34 13s. for engineer's work at the pumping station.

Last week at the Rochdale County Police-court the Urban District Council of Wardle was charged with knowingly permitting to flow into the Ash Brook liquid sewage matter. It was further charged with permitting to flow into the Higher Stock Brook liquid sewage matter. Mr. Wilson conducted the prosecution on behalf of the Mersey and Irwell Joint Committee. Mr. J. T. Worth, who defended the Council, said there was no doubt the Council had permitted an offence to be committed. It had already spent on its sewage works close upon £7000. They had met difficulties with the owners of property, who put their sewage into old stone drains and refused to connect them up with the sewers. The magistrates imposed a fine of £2 in each of the two cases, and made an order requiring the Council to abstain from polluting the brooks in the future.

A Local Government Board inquiry was held last week at Shenfield, concerning the application of the Billericay Rural District Council for permission to borrow £4900 for sewerage purposes for the parish of Hutton and for that part of Shenfield which is not included in the South Weald and Shenfield special drainage district. Mr. C. Edgar Lewis, Clerk to the Billericay Rural Council, said the population of Hutton was 458, and that of Shenfield 1160. The assessable value of Hutton was £3207, and that of Shenfield £6916. The outstanding loans were: Hutton, £941; and Shenfield, £4878. The loan was required for the Shenfield and Hutton joint drainage scheme and the Shenfield Common sewer extension scheme. The latter would amount to £2800, and would be a charge on Shenfield only. It was the intention of the District Council to abate a nuisance which had existed for a considerable time. At present the sewage ran down an open ditch, and was a source of great danger to health. It was proposed to lay and connect a sewer with the Shenfield and Hutton system at the corner of Priest-lane, and the sewage would be treated at the Shenfield outfall works. Mr. Bailey Denton, engineer, explained the scheme in detail and submitted plans.

A Local Government Board inquiry has been held at Leicester with reference to the application for sanction to borrow £2570 for works of sewerage in Hinckley-road and Palmer-street, Belgrave. The application was not opposed.

A report has been submitted by the North Ayrshire District Committee with regard to the new drainage scheme for Dreghorn, in which it has been agreed that the scheme advised by Mr. Copeland, C.E., be recommended for adoption at an estimated cost of £3600, including cost of disposal works.

Colonel W. R. Slacke, R.E., conducted an inquiry at Colne last week into an application by the Corporation for leave to borrow £11,161 for sewage disposal purposes, including the construction of works on the boundary of Trawden. There was no opposition. The Town Clerk (Mr. A. Varley) said the present flow of sewage was 563,496 gallons per day, and it was proposed to provide for a two days' flow.

At the last monthly meeting of the Doncaster Rural Council it was resolved that the Council join the West Riding District Councils Association. The Clerk's estimate of a rate of 1d. in the pound for sanitary work and 4d. in the pound for highway expenses was approved, and the Clerk was authorised to apply to the Local Government Board for sanction to borrow £11,725 for the Conisborough and Denaby sewage scheme, and for £2960 for the Thurnscoe sewage scheme.

At a meeting of the Philosophical Society of Glasgow last week, Professor Glaister read a paper on "Sewage Disposal and Sewage Purification." The various modes of disposing of sewage without purification were described, and special attention was paid to the enlarged Glasgow scheme. When the new sewage scheme is inaugurated at the works at Dalmarnock, Braehead, and Dalmuir, the total daily quantity of sewage to be dealt with will vary from one hundred to two hundred million gallons, the amount depending on the state of the weather. From the results of experience at Dalmarnock it is estimated that the annual amount of sludge to be treated will be between a million and a million and a-quarter tons of wet sludge, and from one hundred to a hundred and twenty thousand tons of pressed sludge. This problem, he continued, is too important for the citizens to avoid taking an interest in, and he hoped that some official pronouncement would be made regarding what the Corporation intend doing in the matter, so that it may be subjected to intelligent criticism before final adoption.

Up to the present time the sewage from the parishes of Winshill and Stapenhill, in the Burton borough, has been turned into the river Trent untreated. These two places have a population of about 10,300, and the number of inhabited houses is estimated at 2000. There has for some time been public protest against this mode of sewage disposal, and at its meeting last week the Burton Town Council had under consideration an important report from the Highways and Sewers Committee recommending the adoption of a complete system of sewerage for the two places named, prepared by the Borough Surveyor, Mr. Lyham, and estimated to cost £47,500. The plan and report embrace a main intercepting and outfall sewer, estimated to cost £16,582; intercepting and branch sewers, £21,696; ventilation, £1774; easements, contingencies, and engineering expenses, £7448. The Committee recommended that the report and plan should be adopted, and that the Surveyor should prepare the necessary plans, sections, and estimates for obtaining the sanction of the Local Government Board to the borrowing of the necessary money; and, further, that the Highways and Sewers Committee should be authorised and directed to carry out the scheme in the name of the Council.

Some little difficulty is being experienced in connection with the southern or Fulshaw scheme of sewerage, for which several thousand pounds has been borrowed by the Wilmslow District Council. A sewer has been laid at a great depth in Sandycroft-road, which connects the Gravel-lane scheme with the new sewer now being constructed through Fulshaw Park, an important residential part of the Wilmslow district. The cutting in Sandycroft-road is causing no little trouble and expense. Certain house property on one side of the road belonging to a Mrs. Royle has already had to be taken down, and a heavy claim has been sent in to the District Council. It is feared, however, that further claims will be sent in to the Local Authority. The Fulshaw Park scheme has yet to be completed, and then Harden Park, where a number of large mansions are situated, will be taken in hand, which will necessitate the breaking up of a long length of the Wilmslow and Alderley Edge main highway. Nearly £30,000 has already been borrowed for sewerage works in the Wilmslow and Fulshaw districts.

WATER.

The Ilkeston Town Council has decided to promote a Bill in Parliament for the provision of a water supply for Ilkeston and Heanor. The scheme is to cost £128,000.

A Local Government Board inquiry has been held at Ryde by Mr. A. A. G. Malet, A.M.I.C.E., into the application of the Corporation for sanction to borrow £1550 for works of water supply.

Colonel Slacke, R.E., held an inquiry at Towcester last week with reference to an application by the Rural District Council for sanction to borrow £1400 for works of water supply for the parish of Towcester.

A special meeting of the Llanelly Urban Council was held last week, for the purpose of sealing the receipt for an order of payment of £5000, being the fourth instalment from the Public Works Loan Commissioners on account of £39,500 required for the new reservoir.

It was reported at a recent meeting of the Heckmondwike District Council that the profits of the united Waterworks Board (Dewsbury and Heckmondwike) for the past year had been £5000, £1250 of which was Heckmondwike's share, or £300 more than last year.

An immediate start is to be made at Andrew with the work of laying the new water main from the waterworks to the town. The contractors (Messrs. Mitchell and Sons, Dundee) were in the town last week and made arrangements for the work being begun. It is expected that the laying of the main will occupy a couple of months, after which the augmented supply of water will be available.

At a recent meeting of the Kintore Town Council the principal business was the consideration of a report from Dr. Watt, Medical Officer of Health for the Burgh, recommending the immediate introducion of a new water supply. After some discussion, the matter was remitted to a special committee, consisting of Provost Marshall, and Councillors Smith and Lindsey, to go into the whole matter, to examine the proposed source of supply, and report when steps would be taken to meet Dr. Watt's recommendations.

A Local Government Board inquiry was held at Clifton last Friday with reference to the application of the Halifax Rural District Council to borrow £6350 for the purchase of the Clifton Water Supply Company, Limited, which supplies the villages of Clifton and Hartshead with water. It was stated that the company got its water from the Halifax Corporation on advantageous terms, and that the price to be paid by the Council for the undertaking had been mutually agreed upon.

The London County Council Water Bill came before the House of Commons on Tuesday, when the second reading was rejected by a majority of 77. The Government promises a measure next year.

A special meeting of the Yeovil Rural District Council was held recently for the purpose of executing the deed of mortgage by the Council to the Public Works Loan Commissioners of the rates of the parish of Montacute, to secure £1300 and interest, the loan being for purposes of water supply for Montacute.

Mr. M. K. North, C.E., an Inspector of the Local Government Board, visited Newbiggin last week and examined the existing sources of water supply, and also viewed the route of the water mains proposed for the new water supply for the town, which the Council has adopted, as designed by Messrs. D. Balfour and Son, civil engineers, including the source of supply, with site of additional storage accommodation.

After a hearing of nearly three hours before a Committee of the House of Lords last week, a partial compromise was effected on the Bill promoted by the Prestatyn Urban District Council with the object of compulsorily acquiring the water undertaking of the town and neighbourhood, and it is expected that an agreement will be arrived at in regard to the other points in dispute. Finally an adjournment was taken to give the promoters an opportunity of seeing whether an agreement could be reached with Lord Windsor and the other petitioners in respect of compensation water.

The Hartlepools Gas and Water Transfer Bill has come before the Court of Reference on *locus standi* in the House of Commons, the petition objected to being to the Sunderland and South Shields Water Company. Mr. Lloyd, who appeared for the Sunderland and South Shields Water Company, argued that they had a right to appear when the Bill came before the Committee, as there were clauses in which it would enable the promoters to supply his district. Mr. Fitzgerald, for the Bill, expressed his willingness to alter the wording of one of the clauses, the effect of which would be to require the consent of the Sunderland and South Shields Company before going into their district. The *locus standi* of the petitioners was disallowed.

Last week the Salford Corporation Water Bill was before a Committee of the House of Lords, presided over by Lord Newton. The measure is one to enable the Salford Corporation to procure from the Corporation of Manchester a daily supply of water beyond the 2,000,000 gallons which they are now entitled to receive in bulk, and for which a price of 3d. per 1000 gallons is charged under the statute. The conditions on which the Bill suggests that this extra supply shall be obtained are that three months' notice shall be given, the notice to state the point of delivery and the pressure required, the quality of the water to be the same as that supplied to the city of Manchester. If the Manchester Corporation is dissatisfied with the price named, the matter is to be settled by arbitration.

Dr. Best gave an instructive address at the Liberal Club, Louth, last week, on the question of the purchase of the Louth Waterworks by the Corporation. His argument was that the present worth of the waterworks undertaking was about £9000, and yet the Highways Committee of the Corporation had unanimously recommended its purchase at £15,000, and this recommendation had only been defeated in the Council by a majority of one. He showed that at the present time only one-third of the people of Louth were using the water, and he argued that it would be quite unfair and most unjust for the other two-thirds to be compelled to pay their share of the cost for the benefit of the other third. He also showed that the income of the company was ridiculously small, and that its £10 shares in the open market realised under £5. The original cost of the undertaking was about £20,000.

LIGHTING.

The electric lighting mains are now being laid in the streets of Maidstone.

A Board of Trade inquiry has been held at Pinner, with reference to the application of the Pinner Gas Company asking for additional powers for extending their works and for further capital.

At a meeting of the Treasurer's Committee of the Edinburgh Town Council last week, a deputation was received from the Edinburgh and Leith Gas Commissioners, who requested a loan of £200,000 from the city funds. It was agreed to give the loan at 3¼ per cent. for forty years.

The Wirksworth Gas Company's report states that the directors propose to declare a dividend of 8 per cent. for the past year, and place £50 to the reserve fund account. The surplus amounts to £453 5s. 4d. On the net revenue account the directors paid a dividend at the rate of 3½ per cent. on April 5th, absorbing £175.

It appearing from the report of the directors of the Northfleet and Greenhithe Gas Company for the half-year ended December 31st last that it was not anticipated that the late high price for coal would be maintained, the Clerk of the Council has been directed to write the company asking that the price of gas to the public lamps and public offices should be reduced to the price it stood at before the last increase after the end of this month.

The Select Committee of the House of Commons resumed on Friday the consideration of the Heckmondwike Gas Bill, the object of which is to establish a Joint Gas Board for the two districts of Liversedge and Heckmondwike, and to transfer to this Board the undertaking of the Heckmondwike Gas Company. Further evidence was now called in support of the promoters' case. The Committee finally found the preamble not proved, and that the promoters had not proved their case.

If the Local Authorities on the north of the Thames are not very much alive, there is a prospect of the ratepayers having to pay a considerably increased price for gas to street lamps. The Gas Light and Coke Company, at the present time, are bound to supply the public lamps on this side of the river at the same price as charged by the South Metropolitan Company, which is now 2s. 8d. per thousand feet. This is 9d. per thousand less than the Gas Light and Coke Company are charging to private consumers. If the Bill which is being promoted by the company, to transfer their undertaking on the south of the Thames to the South Metropolitan Company, is passed, they will be released from this obligation. The cost of public lighting would be considerably increased if the same price as charged to private consumers, 3s. 5d. per thousand feet, were made.

A special meeting of the Sheffield Chamber of Commerce has had the Yorkshire Electric Power Bill under consideration. After hearing a deputation from the promoters, more particularly with reference to a new clause relating to the supply of energy, the following resolution was passed:—"That this Chamber, having considered the Bill of the Electric Power (Yorkshire) Company, and having regard to the fact that the rights of the Sheffield Corporation have been provided for and saved under the new 40th Clause of the Bill, do hereby declare that in their opinion the company's Bill is concerned in the best interests of the commerce and industry of this locality, and that it must be a great advantage to traders generally that central power stations should be established for the generation and distribution of electric power for motive and general manufacturing purposes at the lowest possible cost. The Chamber is prepared to support this principle by evidence before the Parliamentary Committee which will consider the Bill, if this be deemed necessary."

The Local Government Board has written the Newtownards District Council that it has recommended to the Board of Works loans of £3250 for gasworks extension and £160 for market improvements.

The Poulton-le-Fylde Gas Bill came before Lord Newton's Committee of the House of Lords last week. It provided for the purchase under certain conditions by the Urban Council of the gasworks of the Poulton-le-Fylde Gas Company, and for the Council to supply the district with gas. The gas company originally petitioned, but when the Bill was called it was stated that the parties had agreed, and the Bill was accordingly sent to Lord Morley as an unopposed measure.

The Board of Trade inquiry into the electric lighting regulations reached its final stage on Friday, when Sir Courtenay Boyle again attended at the Westminster Town Hall to hear speeches of counsel. Mr. Glen, speaking for the Paddington Borough Council, replied to Mr. Balfour Browne's contention that the change was indirectly for the benefit of the consumer. If that were so, the persons who would derive most benefit would be those whose installation did not require alteration. Why should not those people whose installations did require alteration benefit to the same extent as the others? They would not do so even indirectly, unless they were placed in the same position as if their installations had been the same as the others in the first instance. It was admitted by Professor Kennedy that there would be no difference in the light from the change, and that it was possible the 100-volt lamp was more economical. If that were the case, surely it must be to the detriment of the consumer to force him to use in all cases the 200-volt lamps. As to Professor Kennedy's tests, they were made upon lamps which were sent to him at his own request, and were naturally selected as the very best lamps obtainable. Mr. Danckwerts, for the City of London Corporation, said that it was true that a perfect installation for 100-volt lamps would answer in the case of a 200-volt lamp installation, but he submitted that men of business must know, from their experience of the British workman, that the probability was that a perfect installation did not exist, except, perhaps, where the arrangements had been carried out by the engineer himself. The Board of Trade was asked to deprive people of a vested right. Wherever a vested right was proposed to be taken away it was a root principle in this country that it must be shown that a public benefit, and not a mere private benefit, would result. Tested by that principle, the proposal must fail, and he submitted no case had been made out at all by the electric lighting companies.

GENERAL.

The Whitehaven Town Council is about to purchase and repair the baths and wash-houses in that town.

Mr. A. A. G. Malet, a Local Government Board Inspector, held an inquiry at Kingswood last week, respecting the application of the Urban Council to borrow £2000 for street improvements.

On Wednesday in last week Mr. E. A. Sandford Fawcett held an inquiry on behalf of the Local Government Board at Tunbridge Wells, with reference to an application by the Town Council for two loans, namely, £1800 for street improvement and £10,000 for establishing a municipal telephone system for the borough of Tunbridge Wells.

In the picturesque village of Allesley, Warwickshire, an ancient custom which is found to linger here and there, is still observed. The church bell is rung at five o'clock every morning in the summer, and at six o'clock in the winter, in order to arouse sleeping villagers, and enable them to start work in good time. The curfew bell is also tolled at eight o'clock each evening.

We understand that the Urban District Council of Farnworth has some large schemes under consideration. It is proposed to spend £40,000 in street works and improvements, £14,000 in the erection of public buildings, and £5000 in works of sewerage and sewage disposal.

With reference to the case of plague reported at Southampton, says the *Times*, the utmost precautions have been taken to prevent the possibility of its spreading. Dr. Reece, of the Local Government Board, has been in consultation with the Local Authorities with this end in view. It appears that the affected lascar was a steward in the Simla, and was taken ill shortly after the vessel left Cape Town. The Simla called at Plymouth before proceeding to Southampton, and was there given a clean bill of health; in consequence she came direct into dock. Had she not called at Plymouth she would have anchored off Netley until boarded and passed by the Port Medical Officer, plague regulations having for some time been in force at Southampton. It is expected that the outbreak will not interfere with the transport arrangements save in respect to the Simla herself. Dr. Reece also visited Plymouth on Friday last, and he has been satisfied that no blame attaches to the Medical Officer of that port for not diagnosing the case as one of plague. As a matter of fact, no report of the illness of the patient was made at Plymouth, nor, indeed, until two days after the ship's arrival, at Southampton.

The public inquiry into the application of the Leeds Corporation for the issue of a Provisional Order confirming an improvement scheme under the Housing of the Working Classes Act, 1890, by which it is proposed to deal with the Quarry Hill insanitary area, was resumed before Mr. R. H. Bicknell, M. Inst. C.E., an Inspector of the Local Government Board, at the Leeds Town Hall, last Friday. Mr. Jeeves, the Town Clerk, in concluding his speech, submitted that the Corporation was not acting improperly; but, on the other hand, was acting most properly, in the discharge of a duty, the importance of which must be increased and added to every day. There was, perhaps, no more crying question at the present day than that of dealing with unhealthy houses and the housing of the working classes generally, and if the Corporation did not take the matter up, it would not be fulfilling its public duty. It was no pleasure to the Corporation to carry out such schemes, because they involved an increase of the rates. He left the matter with all confidence in the hands of the Inspector, believing that he would deal with it in the broad light of the Act, and not in the light of the narrow interests of individual pockets.

The new refuse destructor at Greenbank, erected by the Blackburn Corporation in order to cope with the heavy quantity of refuse which is daily taken off the streets, has been working successfully now for several weeks, and recently the members of the Sewage Committee inspected the works. In Blackburn 1000 tons of refuse per week are dealt with, and of this amount 400 tons is disposed of at the Audley destructor and 40 tons at the Storeyard destructor. Great difficulty was experienced by the Corporation in obtaining suitable sites for tipping the surplus refuse, both within and without the borough very strong objections being raised on account of the offensive smell given off, and also of the unsightly nature of the refuse. To meet this difficulty, on the recommendation of the Borough Engineer, the Committee decided to erect another destructor on a plot of land adjoining the new gasworks at Greenbank, and to generate the steam necessary for driving the engine and other plant required in the manufacture of gas. The works have so far given every evidence of being able to do the work which was guaranteed by the contractors. The cost of the land, buildings, machinery, &c., has been £9000.

The Devon County Council has adopted a recommendation of the Finance Committee to lend the Newton Abbot Hospital Committee a sum of £6100, the estimated cost of providing a joint isolation hospital, according to plans sanctioned by the Local Government Board.

A recommendation to the Liverpool City Council has been adopted by the Health Committee of the Corporation to the effect that 100 guineas be granted towards the expenses of the International Congress on Tuberculosis which is to be held in London in July next. The hon. secretary of the Liverpool branch of the Congress is Dr. Nathan Raw, of Mill-road Infirmary.

The Sanitary Commissioner with the Government of India draws attention, in his last report, to the significant fact that, although *beri-beri* disease has long existed in Burma, and occurs in certain districts of Madras, no case of it has ever been recorded in the wheat-eating areas of India. In Rangoon, Hindoo natives of India appear to suffer most. Those attacked belong almost entirely to the coolie class, chiefly from Southern India, and are generally people whose diet, though it may be plentiful, is very deficient in nitrogenous elements. In the past three years close on a thousand cases of *beri-beri* have been admitted into the Rangoon hospital, very little more than half of them recovering. The death-rate, indeed, is returned as 48 per cent. of the 944 cases registered. This means more than 400 deaths.

Dealing with the old sore of insanitation, Dr. Palmer says there is nothing of the nature of "the housing problem" in Newtown, but that the rate of mortality is materially influenced by the density of population in courts and alleys, a real sense of which he strives to instil into the mind of the Sanitary Authority. Yet a close examination of the Doctor's report, remarks the local paper, would indicate that the housing question in Newtown is every bit as serious as that of Welshpool, for he observes, "the urban portion of the district is honeycombed with courts and alleys, and I believe the inhabitants of these unhealthy places would be glad to come out into the open if suitable accommodation were provided." The character of these unwholesome holes may be imagined when, from a sanitary point of view, the Doctor contends they can only be effectively dealt with by dynamite. It is satisfactory to learn that the notorious "Lot" has been improved "beyond recognition," but the "exasperating slowness" which attends the improvement of other slums should sharpen the determination of the Sanitary Committee to thoroughly accomplish the important work upon which they are engaged.

The disposal of town refuse in South Shields has long been a matter which has given rise to a serious consideration in the South Shields Corporation. The present system consists of the removal of refuse to the staith on the riverside, from whence it is taken to sea, and the supplying of farmers and others inland with quantities. With respect to the latter method an increasing difficulty has been experienced in getting rid of the refuse, and the establishment of depôts in the town has also been most unsatisfactory. Lately the question has reached an acute stage, and at a meeting of the Health Committee last week a decisive step was taken. The Committee, after some discussion, resolved to recommend the Council to adopt the principle of a refuse destructor, and their recommendation will come before the next ordinary meeting of the Council. It is in every way probable that in order to obtain some idea of the working of these destructors a deputation may visit Glasgow, Leeds, and other places. It is suggested that the destructor should be established on a site in the neighbourhood of the Deans. The cost of the provision of such a destructor would be anything from £18,000 to £20,000, though until the details are known the exact amount cannot be definitely estimated.

Colonel C. H. Luard, R.E., held an inquiry at Nottingham recently with reference to the applications of the City Council to borrow £24,000 for purposes of street improvement in Parliament-street, Nottingham, and £10,000 for the reconstruction of the Carrington-street Bridge.

PERSONAL.

Dr. Logan and Dr. Joyce have been reappointed Medical Officers for Ashley.

Mr. E. Brooke, of Brighouse, Yorks, has been appointed City Surveyor for Lichfield.

Dr. Fox has been reappointed Medical Officer for Walsall, and Mr. Jackson as Inspector.

Dr. Elliott has been reappointed Medical Officer of Health for the rural district of Oundle.

Dr. Thresh has been appointed Medical Officer of the Chelmsford Rural District Council's isolation hospital.

Dr. Smithies has been reappointed Medical Officer of the Gisburn district of Clitheroe for twelve months.

Mr. H. J. Norris has been reappointed Inspector of Nuisances for Herne Bay, at a salary of £120 per annum.

Dr. Behrendt has been reappointed Medical Officer for the urban district of Scunthorpe, at a salary of £45 per annum.

Mr. John Barritt has been reappointed Inspector of Nuisances for Kettering, at the increased salary of £130 per annum.

Dr. J. A. Goodall and Mr. Margereson have been reappointed Medical Officer of Health and Surveyor respectively for Brampton.

Mr. Thomas H. Scott, C.E., Edinburgh, who belongs to Selkirk, has been appointed Burgh Surveyor and Sanitary Inspector of Peterhead.

Mr. G. F. Beecher has been appointed Medical Officer for the south-east district of the Sheffield union, in room of Dr. E. W. Adams resigned.

Dr. William Sedgwick Saunders, Medical Officer of Health for the City of London, who died on January 18th last, left personal estate of the net value of £36,836, and the whole of his estate has been valued at £38,170.

LAW CASES.

A Sanitary Inspector's Appeal.

The High Court of Justiciary at Edinburgh disposed last week of an appeal taken by John Frew, Sanitary Inspector for the county of Linlithgow, against the decision of Sheriff-Substitute Macleod, acquitting Thomas Gunning, dairyman, Kirkliston, of a charge of contravening the Food and Drugs Act. The complaint was that the respondent on 5th December, 1900, on the public road in Kirkliston, sold to the appellant two pence worth of sweet milk, which was not of the nature, substance, and quality demanded, in respect that it contained 13 per cent. or thereby of added water. It was proved that when the Inspector asked for the milk the respondent was about to supply him out of a can which contained the produce of his own cows, but the Inspector refused to have it, and desired to be supplied out of a large barrel. Before supplying him the respondent informed the Inspector that the milk in the large barrel had been purchased by him, and that it might or might not prove to be sweet milk. On these facts the Sheriff decided that, as the appellant had been supplied with the article which he insisted on getting after warning, the respondent was entitled to an aquittal. The Sanitary Inspector appealed, but the High Court confirmed the decision, and dismissed the appeal, with seven guineas of expenses.

Vitiated Air in Workrooms.

With the approval of the Home-office, Miss Lucy A. Deane, one of his Majesty's Inspectors of Factories, summoned to Westminster Police-court Mr. Hulbert Beach, court dressmaker, Sloane-street, under Section 32 of the Factory Act of 1895, for failing to take adequate measures for securing and maintaining a reasonable temperature in his workrooms, where many young women are employed.

Miss Deane said this was a very important prosecution, the first of its kind—which affected the comfort and health of many work-girls. It was not a question of working in excessive cold or heat, but of the way in which the temperature in winter of workrooms was maintained—viz., by shutting doors and windows, so that the heat generated from the bodies of the workers and from gas jets warmed the place. Anything more foul and unwholesome could not be imagined—such workshops became perfect hotbeds of consumption and other diseases.

Mr. Sheil said the section of the Act did not refer to ventilation but to temperature.

Miss Deane: There is no other section by which we can meet cases like this.

Mr. Sheil said he thought it was a shocking state of affairs as described by the Inspector, but he could not strain the law. The Legislature should alter it.

Miss Deane contended that the very narrowest interpretation should not be placed on the section. Would his Worship hold that "a reasonable temperature" would be maintained, say from the poisonous fumes of a charcoal brazier? Surely it was a case for a broad view.

Mr. Sheil: I beg your pardon. This is a criminal case, and I must construe it strictly.

Miss Deane: May I suggest that this section was drawn to meet an almost illimitable field of contingencies?

Mr. Sheil: You cannot speculate about that. If Parliament does not provide against workers being poisoned and asphyxiated with foul air, I can't help it.

Miss Deane said she had instructions to ask for a case, and therefore she wished to be sworn. In evidence she stated that she visited two dressmaking and tailoring workrooms on the defendant's premises, where "the heating apparatus" on a winter day consisted respectively of fourteen and eleven young women and numerous gas jets. The windows, &c., were tightly closed and the fire-grates removed. The air was vitiated and extremely foul.

Dr. Louis Parkes, Medical Officer of Health for Chelsea, said that girls working in such unhealthy conditions must be seriously affected. The defendant denied cases of illness, or that the workshops were unhealthy.

Mr. Sheil said he regretted to be obliged to dismiss the summons. He considered that such an abominably unwholesome state of things should be remedied.

Miss Deane reiterated her request for a case.

Mr. Sheil: Yes; but you had better get the opinion of the law officers before you go on.

NOTES AND QUERIES.

Subscribers may obtain advice on matters appertaining to Public Health Law and Municipal and Sanitary Engineering. Letters should be addressed "Notes and Queries," The Sanitary Record, 5, Fetter-lane, London, E.C. If an answer be required immediately, a stamped addressed envelope must be enclosed

2129.—Landlord and Tenant: Insanitary Dwelling-house.—"H. V. P." writes:—"I have recently taken a house, and find the following irregularities in the sanitary arrangements: (1) Inside water-closet has a very old pan, water-closet which after being used and flushed becomes quite dry, consequently there is always a stench arising therefrom. (2) Two outside water-closets also very old pans, and I am unable to flush these at all. (3) Two rain-water cisterns in a very dirty state. (4) Main cistern (outside, but well covered) in a very dirty state. (5) There is no dustbin of any kind. (6) The kitchen range is quite useless. Will you please advise whether I can compel the landlord to make good the before-mentioned defects, or whether the matter rests with me as tenant? I have not the house on a repairing lease."

Answer.—In the absence of express stipulation a landlord is at common law, not compellable to do any repairs whatever to an occupied dwelling-house. He may, however, if he chooses, take upon himself to do all or any of the repairs during the term of tenancy. A tenant should ensure before entering into occupation of a dwelling that it is reasonably fit for human habitation, and if the landlord fraudulently represents that it is fit for human habitation when such is not the case, and injury to health is caused to the tenant or any members of his family by defective drains, dampness, or vermin, an action will lie at the suit of the tenant against the landlord. With respect to the insanitary and other defective conditions described by the querist, he should give the landlord the opportunity of doing the work, and after reasonable notice, if such work be not carried out, then he should write to the Inspector of Nuisances of the Local Sanitary Authority whose duty it will be to visit the premises; and if he finds that any nuisance exists owing to structural defects, such as those mentioned, he must make a report to the Sanitary Authority, who may serve notice upon the owner to carry out such work as they may direct to abate the nuisance.

2130.—Isolation Hospital: Sewage Disposal Scheme.—"M. O. H." writes:—"Could you please suggest the best method of treating the sewage from a small isolation hospital of ten beds, where sewers are not available?"

Answer.—Either the septic tank system, or the "Dibdin," or Sutton system, can be safely recommended. The querist is advised to read Martin's "Purification of Sewage by Bacteria," price 6½d., post free; and Dibdin's "Purification of Sewage and Water," price 21s.; or Thudichum's "Bacterial Treatment of Sewage," price 1s. 3d., for further information on the subject. Any of the books may be obtained from the office of this journal.

2131.—Combined Drainage: Drain or Sewer.—"X. Y. Z." writes:—"In a terrace of nine houses the first house belongs to Jones and the remainder to Brown. All the nine houses drain into one common drain at the back, and before joining the public sewer in the main street they unite in a private passage-way with the drain from the six houses belonging to Robinson. I contend that the drain crossing the gardens of Nos. 2 to 9 is a portion of a single private drain. The Public Health Acts Amendment Act, 1890, is in force, and action is being taken under Sec. 41 of the Act of 1875. Do you think my contention is correct?"

Answer.—We have considerable doubts as to whether the combined drain receiving the drainage of the eight houses belonging to Brown can be deemed to be a private drain. The house No. 1 belonging to Jones is not connected to the common drain constructed by Brown, and therefore Sec. 19 of the Act of 1890 does not appear to apply. The houses are not within the same curtilage. We think the better opinion to be that the common drain is a sewer, and vested in the Local Authority.

2132.—Combined Drainage, Drain, or Sewer.—"J. S." writes: "I enclose plan showing a block of houses drained by a combined drain, and shall be obliged for your opinion as to whether the drain is a drain or a sewer?"

Answer.—The drain is a single private drain and not a sewer. The houses connected to the drain are within the same curtilage, and the owner is liable for the repair of the drain.

2133.—Privy System: Cleansing of Privies.—"H. C." writes:—"In our district the privy cesspool system is in use. The ashes are kept entirely separate. We experience much difficulty at times in cleansing the privies owing to children casting tin cans, brickbats, and any useless rubbish into them. Have we any remedy; does the Public Health Act help us at all by making the owner or occupier of the property liable for the improper use of the privy."

Answer.—There is no provision in the Acts directly affecting the point raised. A Local Authority may, however, in our opinion, reasonably refuse to remove the contents of any privy which is improperly used. Sec. 43 of the Act of 1875, it may be observed, prescribes a penalty against a Local Authority who have undertaken or contracted for the removal of house refuse, &c., when they fail, *without reasonable excuse*, after notice in writing to remove such refuse. In our opinion the misuse of the privies will justify the Local Authority in refusing to remove the refuse, for such nuisance will constitute a "reasonable excuse." The Local Authority are advised, however, to issue notices to the occupiers before taking the step indicated, when the practice will no doubt be greatly lessened.

STANLEY
Government Contractors.
Makers of Mathematical, Drawing and Surveying Instruments of every Description.

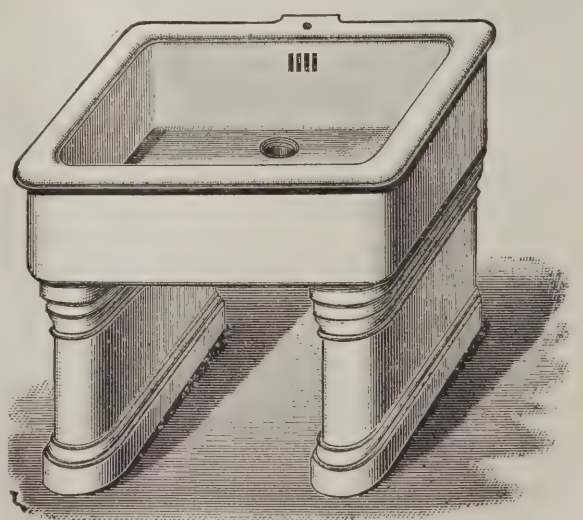
CRAIG'S WHITE GLAZED FIRE-CLAY SINKS
On White Glazed Fire-Clay Supports.
In appearance nearly equal to Porcelain, which they greatly excel in strength and durability. Admirably adapted for use in Kitchens, Sculleries, Butlers' Pantries, Laboratories, &c. Extensively used in houses of the better class, and in many important buildings throughout the country during the last thirty years.
Adopted by H. M. Board of Works, H.M. Commissioners of Prisons, &c.
Awarded First Prize Medal by the Sanitary Institute of Great Britain



J. & M. CRAIG, Ltd., KILMARNOCK

SEWAGE DISPOSAL AT CREWE.*

The sewage of Crewe, which is practically domestic —not containing much trade effluent—is at present dealt with at the sewage farm which was laid down in 1872 at a capital expenditure of £47,000, and which has an area of 260 acres. This whole area has a subsoil of stiff clay. Willows and rye grass grow upon the farm.

The sewage flows by gravitation to the lowest portion of the farm along two main outfall sewers; the northern capable of taking 14 million gallons in twenty-four hours, and the southern with a like capacity as far as the gasworks in Victoria-avenue, but beyond that point only equal to 10 million gallons in twenty-four hours. The sewage is pumped untreated, and is delivered by elevated and ground-level carriers at whatever point is desired. The pumping is done by a beam engine, which can lift 100,000 gallons per hour. After passing over the land, the effluents flow into two streams, the North Brook or the South Brook, each of which ultimately discharges into the river Weaver.

Owing to the facts that the subsoil is stiff clay, and that the population of the town is rapidly increasing, and this method of sewage disposal not proving altogether satisfactory, it has been decided to dispose of the sewage from the northern outfall (about one-fifth of the total quantity) by the bacterial method. Excavating operations are in progress at the present time, and it is expected that the bacterial beds will be ready for use about next June.

The following is a brief account of the lines which will be adopted:—The sewage will pass from the northern carrier direct into a detritus tank, thence passing through screened openings (to keep back paper, rags, and other matters which are not properly sewage) into an open septic tank of sufficient capacity to hold one day's sewage. This septic tank will measure 186ft. by 50ft., will rise from 9ft. to 10ft. 6in., and will have a capacity of 70652·96 cubic feet. This tank will have its walls and bottom lined with blue brick and cement, and in this part of the process the anaërobic organisms will act in such a way as to liquefy the solid excreta. The fluid sewage will pass through this tank slowly, and be drawn off about 2ft. below the surface by means of Adams' automatic distributing apparatus on to a primary bacteria bed. The distributing channel will be of shallow depth to allow of the aëration of the sewage as much as possible.

There will be five primary and five secondary beds, and the tops of these secondary beds will be about 1ft. below the bottom of the primary beds. Each bed will measure 71ft. by 41ft. approximately, and will have a cubic capacity of 16,089 cubic feet. In this part of the process the aërobic organisms will have full play, and convert the liquefied organic matter into more stable, non-putrefactive substances.

The operation of filling the beds will take place as follows:—Bed No. 1 first commences to fill through the sewage inlet feed. The sewage rising in the bed locks air within a dome connected to the feed, which creates sufficient pressure to cut off the supply when the primary bed is full. At the same time it releases the feed to bed No. 2, which then begins to fill, stops off, and releases feed to No. 3 in the same manner, and so on throughout the series. When the bed is full the sewage is held up for the desired period of contact, which is governed by the filling of the small chamber in which the withdrawing syphon is placed with effluent from the bed, which enters through a tap. The tap may be altered to give any desired period of saturation.

When the chamber is full the syphon discharges, withdrawing the liquid contents of the primary bed, and delivering on to the corresponding secondary bed below, where it is again held up for contact in the same manner as before, being finally discharged as effluent into the brook.

After a bed has been emptied it remains open for aëration until each other bed in the series has been filled in turn, when the supply is again brought on, all the requisite operations being brought about in proper sequence, without movement or attention.

The beds will be arranged so that each may be worked on an eight hours cycle, that is to say, approximately—two hours for filling, two hours for standing quiescent whilst the bacteria are doing their work, one hour for drawing off the effluent, and three hours standing empty for aëration. Arrangements will also be made for resting each pair of beds for one day in every eight days for recuperation and aëration; also the scheme allows for drawing off of 4ft. 6in. of effluent, only leaving 6in. approximately in the bed.

It is proposed to construct the beds, &c., as follows:—The tank will be excavated in such a way that its sides will slope two to one, and will then be covered with a 6in. layer of concrete floated up to a smooth surface. The distributing channels and beds will be constructed in like manner, but with a 4in. layer of concrete only. Upon the bottom of the filter beds a central line of dry brick effluent drains will be laid with open joints, and radiating lines of 4in. common land drain pipes, also open jointed, arranged herring-bone fashion, placed 3ft. apart and running into the brick mains. The material used for filling the beds will be screened clinker obtained from the London and North-Western Railway Works, and not more than 1½in. gauge or less than ¼in. gauge. The whole of the material will be washed and screened under the Borough Surveyor's supervision before it is placed upon the beds. Upon the surface of the filtering media wooden distributors are to be placed, to consist of a 6in. main with 4in. side branches spaced 6ft. apart, pierced with ⅜in. round holes both in bottom and sides of the trough at intervals of 18in., and to be properly connected up to the syphons. There will be automatic syphons to the beds capable of dealing with 500,000 gallons of sewage per day.

* From the annual report of Dr. Alfred Greenwood, M.O.H. for the Borough of Crewe.

THE NEED FOR A MINISTRY OF PUBLIC HEALTH.

At the last meeting of the Lancashire and Cheshire branch of the Association of Sanitary Inspectors, a paper on the above subject was read by Mr. Fred Scott, F.C.A., secretary to the Manchester and Salford Sanitary Association. We have already given a summary of the paper, but the subject is of such great importance that we now give it in full.

The subject which I have chosen for this paper being one involving questions of high State policy, it would seem presumptuous for an obscure layman to approach it, and if it had not been frequently discussed by persons whose claim to be heard is incontestable, I would scarcely have dared to deal with it. But when such distinguished sanitarians as the late Sir Edwin Chadwick, a past-president of your Association, and the late Dr. Benjamin Ward Richardson, deemed the proposal for the creation of a Ministry of Health worthy of their strenuous advocacy, it seems no more than a respectful tribute to their memory to revive the idea. One never knows how in the ways of Providence things are ordained so that great results sometimes spring from most insignificant beginnings, just as the tiny acorn dropped on suitable soil develops in time into the widespreading and majestic oak tree. The soil in which it seems desirable that this idea of a Ministry of Health should germinate is the brain of an able and disinterested Member of

Parliament or Peer, who sees more utility in mastering and devoting his life to the attainment of one great object than in diffusing his effort over the multifarious questions that are dealt with in one or other of the Houses of Parliament, and failing to make a distinct mark on any of them. Indeed, experience shows that it is only by that concentration of interest and effort which constitutes enthusiasm, persistently applied to the advocacy of any reform in this country, that adequate progress can be made with it, unless, indeed, public opinion is electrified by some great catastrophe.

The late Sir Henry Cole, the organiser of South Kensington Museum, once told me that the late Prince Consort, when asked to help any new movement, invariably asked in the first instance, "Who is your madman?" and had to be assured of the enthusiasm of the moving spirit before he would lend his name. Sir Henry dabbled a little in sanitary reform himself as well as art matters, and he was very fond of relating what he described as a favourite joke of the Prince, viz., that when the latter wanted anything doing in which he thought Sir Henry could help, he sent for him, remarking that he found it impossible to raise steam without coal (Cole). What is wanted is a man not too old to be enthusiastic, but with sufficient ability or experience, or both, to command the ear of the House in which he sits, and who will lose no opportunity of educating Parliament on the advantages of possessing a Ministry of Health. Instances in illustration of this essential factor might be multiplied, but I need only mention the achievements of Mr. Henniker Heaton, M.P., in connection with postal reform, and the late Mr. Plimsoll in respect of protection of seamen. The only other method by which desirable reforms are rapidly effected is the occurrence of some great catastrophe which gives a shock to the public mind, or some severe test of a system which has been allowed to grow up from beginnings based on no well-ordered scientific plan. Of the former, the best illustration is perhaps the sanitary legislation of the past thirty years. It may safely be stated that it was the death of the Prince Consort from typhoid fever, and later the serious illness of his present Majesty from the same complaint, which gave the impetus to sanitary reform and the demand for legislation which provided the present system of health administration. Even such an advanced reformer as Sir Edwin Chadwick had never been able to secure any more efficient form of health administration than the General Board of Health, of which he was the chief executive officer. The effect of testing a system under a severe strain has been well illustrated in the present war, and the War-office, which has, like all our Government departments, grown up under bureaucratic influences, has not appeared to advantage under the test. Thus in delaying reforms in administration until any particular department exposes its weakness and inefficiency under severe strain, we elect to live in a fool's paradise. But, it may be urged, how can the proved inefficiency of the War-office be taken as a parallel for health administration under the Local Government Board? I reply, that we have to judge by results in both cases. It is generally admitted that if our War-office had been efficient the present war could never have become so serious a matter as it has proved, and that the cost of inefficiency has been thousands of lives and many millions of money. For the hundredth time we are going to lock the stable door after the horse has been stolen. But even that object lesson will not move anybody to question the folly of delaying the reform of health administration, and yet issues of vastly greater importance than those depending upon War-office reform are involved. In this war not more than 7000 men have been killed in action and died of wounds, and about double that number have died of disease, say 20,000 in all. But in the United Kingdom there are about 120,000 preventable deaths every year, and yet we accept such a condition of things as if it were inevitable. The most convincing proof of the inefficiency of our system of health administration is the fact that such an enormous death toll for disobedience to the laws of health still exists. The public mind is satisfied with the assurances given from time to time of apparent progress, indicated by reduced mortality from certain diseases, or success in coping with a threatened epidemic. Yet all the time we are, as it were, dwelling in a charnel house, and progress towards that ideal time, when the presence of a case of zymotic disease in any community would be regarded with almost as much wonder as the re-appearance of a specimen of the old British wolf, must necessarily be slow, while we regard our present fearful death toll as inevitable, and contentedly submit to a system which stands as much condemned by our vital statistics as the War-office does by recent events.

It must be admitted that under the present system an excellent organisation for the prevention of disease has been developed; but what is the use of the machinery if the hands of those who could and would work it are more or less tied? It cannot be denied that the extension of Local Government and the devolution of administration in many departments of government in this country has been on the whole highly beneficial, but there are certain matters for which it is essential that the administration should be centralised or at least that the Government Departments should not be merely nominal boards of control, but bodies whose duty it was to see that the law was properly administered by Local Authorities. Thus in the adminstration of justice (Home-office), military affairs (War-office), education (Council of Education), trade (Board of Trade), agriculture (Board of Agriculture), and others, Government itself exerts a direct control, whereas in the matter of health the Local Government Board, even though its President may be a Cabinet Minister, as at present, cannot be said to exert any active control. Of course it has to formally sanction bye-laws, authorise loans, &c., but how rarely is its power employed to require recalcitrant Local Authorities to enforce the law? Indeed it has come to this, that a Local Authority has only to act in defiance of the Board, and it may practically do as it likes. How often does it happen that a municipality has already spent money on a particular work before even asking the permission of the Board to borrow it as required by law, and how often do we see reports of Boards of Guardians and other Local Authorities under the nominal control of the Local Government Board openly treating its communications with contempt? It was only the other day that it was claimed for a neighbouring Local Authority that it had gained a victory over the Board by obtaining permission to do some works of drainage. For years it has withstood the Board in respect of its requirements as regards sewage disposal. Naturally, a Board that is unable to enforce its requirements in such matters must have very little influence in the minor details of health administration. The interests of the public health cannot be properly attended to while they form only a section of the charge of an already ineffective department, and yet are of vastly greater importance to the well-being of the country than most of those interests now forming the sole charge of departments whose chiefs are *ipso facto* Cabinet Ministers.

If the importance of a branch of administration is what determines its claim to be a distinct department controlled by a Cabinet Minister, then health ought to be regarded as second to none. There have been few statesmen whose dictum on this point would be as weighty as that of the late Lord Beaconsfield. When, as Mr. Disraeli, he was Prime Minister, he said, "The health of the people is really the foundation upon which all their happiness and all their power as a nation depend. It is quite possible for a kingdom to be inhabited by an able and active population; you may have skilful manufacturers, and you may have a productive agricul-

ture; the arts may flourish, architecture may cover your lands with temples and palaces, you may even have material power to defend and support all these acquisitions, you may have arms of precision, fleets of fish torpedoes; but if the population of that country is stationary, or yearly diminishes in stature and strength, that country is ultimately doomed. The health of the people is therefore, in my opinion, the first duty of a statesman."

But in estimating the importance of the Public Health Service as a State department, we have something more to consider than a statesman's generalisations, which are liable to be discounted as platitudes used for party purposes, although it is in itself a recognition of the importance of the subject that a party leader should select the subject as one on which his party claimed support. The work of a well-organised Health Department is reproductive. It means the saving of many thousands of lives yearly. Eminent writers such as the late Dr. Farr, the great health statistician, the late Sir John Simon, Medical Officer to the Privy Council, Mr. Humphreys, and others, have endeavoured to assess the money value of a human life, or the difference between earnings and cost of maintenance, and the sum which they approximate to as the average value is £200. Now, taking 120,000 preventable deaths each year, they represent a capital loss of £24,000,000, but every death represents perhaps five cases of sickness, all involving heavy pecuniary loss. Thus on pecuniary grounds alone it pays to secure the greatest possible efficiency in health administration.

But there are more serious considerations still than those of a financial character. The chief is that referred to in the quoted utterance of the late Lord Beaconsfield, which was only stating in prose what Goldsmith so truly expressed in verse—

> "Ill fares the land to hastening ills a prey,
> Where wealth accumulates and men decay."

It has been frequently stated, amongst others by Mr. T. C. Horsfall (on the authority of the late Commander-in-chief—Lord Wolseley, I believe) that there has been a marked falling off in the stature and general physique of the soldiers recruited from manufacturing districts, and this is not to be wondered at when we remember the insanitary conditions under which the class from which the rank and file of the army is drawn, exists. Surely Lord Beaconsfield was right in stating that the country where such deterioration is allowed to go on, is doomed. It is only a question of time; the doom is only delayed while the stamina of the race is maintained by the rural population, but we know that the conditions of population are rapidly changing. Not more than fifty years ago the rural population far outnumbered that in the towns; now the position is reversed, and a much larger population exists in the towns than in the country. In another half century the same process will probably leave a very small population of peasants to recruit from. It seems, therefore, the height of folly, the entire abnegation of true statesmanship, to allow the interests of the public health to remain any longer subordinate to those selfish interests which are now too generally represented in the bodies charged with the administration of the law.

The very fact of recognition by the State of the pre-eminent importance of the interests of the public health, by advancing the controlling department to the rank of a Ministry, would in itself exert a powerful educational influence. But it would do much more. The change would involve many improvements in the organisation of the health service. Thus uniformity, as far as local condition would permit, of the bye-laws of all Local Authorities, the direct responsibility of Medical Officers of Health and Sanitary Inspectors to the Central Authority (this implying security of tenure of offices to such officials, and consequently their independence in seeing to the effective administration of the law); all matters affecting public health would be dealt with by the Health Ministry instead of being divided between the Local Government Board, the Home-office, and perhaps one or two other departments as at present, and a well-organised Health Ministry would supply the standards of sanitary necessities for the army, the Colonies, and other dependencies, thus rendering valuable help to those dapartments. A Health Ministry would have a special care to the perfecting of health legislation, and perhaps one of the first things to be done in this direction would be the alteration of all the "mays" in the Public Health Acts into "shalls." At present it is left entirely to Local Authorities to seek powers as they desire them to meet local requirements, involving heavy charges on the rates, in promoting Bills or Provisional Orders which might at a minimum cost be obtained for them by a Ministry of Health.

I have referred to the work of making local bye-laws as uniform as possible. The importance of this in respect of building bye-laws will be well understood by all present. But to emphasise it I may state that the present building bye-laws of Manchester, which were only obtained after a prolonged agitation by the Manchester Society of Architects and the Manchester and Salford Sanitary Association, would, if strictly enforced, effectually prevent the erection of any more "jerry" property within the city; yet in some of the suburbs the speculative builder is to-day erecting dwellings which in a generation or less must become slums, and thus the evils of the past are being perpetuated. This is a thing in which Local Authorities ought certainly to be controlled by a strong Central Authority.

To you practical men, many other arguments in favour of the creation of a department which would at once greatly increase your power of serving the community, and correspondingly enhance the dignity of your office, must suggest themselves. I have tried to state a few reasons justifying the formation of a Ministry of Health. However feeble my effort, it will be useful if it has no other effect than that of keeping the subject alive, and perchance suggesting to some more powerful pen and influential voice to take it up. Let those who see in the proposal as I do the basis of reforms which would work out the physical salvation of our country, talk with others about it as occasion offers until, on the principle of the snowball, which gains in size and weight as it is rolled along, the proposal may soon come to be a matter which can no longer be ignored by Government.

LEEDS SANITARY AID SOCIETY.

The annual meeting of the Leeds Sanitary Aid Society was held last week in the Lord Mayor's Rooms at the Town Hall, when the Lord Mayor (Ald. F. W. Lawson) presided.

Mr. Michael Teale (hon. sec.) read the annual report, which stated that in the early part of the year several series of lectures were given in various parts on elementary sanitary subjects, dealing chiefly with the disposal of household refuse, the necessity of fresh air and good drainage, and the prevention of the spread of infectious diseases. At the monthly meetings of the Society many of the larger sanitary questions were discussed, questions such as the substitution of public abattoirs for private slaughter-houses, the possibility of ventilating public sewers in a more satisfactory manner, and the housing of the working classes; and at every meeting more detailed matters concerning insanitary conditions in the poorer parts of the city have been carefully considered, and steps taken to bring about an improvement. The Committee were glad that in some cases the Society's intervention had been followed by most satisfactory results. Much of the Society's use-

fulness lay in this latter direction, and accordingly the Committee asked for the co-operation of all members of the Society in observing and bringing before their monthly meetings all nuisances and insanitary conditions among the poor which came before their notice. The importance of leaflets as a means of education in simple but important principles regarding health was pointed out, and their issue is to be continued. Though the Committee have ended the year with a balance in hand, they mention that much of the balance is in connection with the wide circulation of these leaflets. The scope of the Society's work has been seriously limited in the past by lack of funds, and there is much more work which should, and would be undertaken if subscriptions on a larger scale were forthcoming.

The Lord Mayor, in moving the adoption of the report and balance-sheet, remarked with pleasure the increase in the balance, and as to their work, he said he had no doubt that to the inhabitants, especially in such a quarter, for instance, as that in which his works were located—where, to 45 per cent. of the people sanitation was an unknown quantity—it would be a great advantage to the city. Of course, the Corporation, by their insanitary area scheme, involving the outlay of a vast sum of money, were rendering first aid, and it was felt that if they could get rid of the courts and back areas, and let a breeze in among these slums, they would be doing a great deal for the health of Leeds. As regarded public abattoirs, he thought they would find that these were already working, and he believed the butchers of Leeds were very much pleased with them. He did not know whether the Society suggested that they should be put all over the city, for that would be rather difficult, inasmuch as there would be the removal of the refuse; but he understood from Ald. Knowles that the abattoirs they had were working very well. The abattoirs at Copley Hill had not been much used, being rather difficult of approach; and it was very awkward for the public that beasts should be driven through the streets. Now-a-days one heard all kinds of rash proposals, and the latest he had heard was that the carriage of the beasts should be undertaken by the tramways. We lived in an advancing age, and what would be done in the future he could not say, but anything that would prevent the driving of infuriated beasts through such thoroughfares as Commercial-street and Briggate would be a great advantage to the city. In conclusion, the Lord Mayor observed that the Society was doing a very useful work, but in a large city one was apt to overlook it in the multitude of organisations. He was glad to have that opportunity of recognising the fact by asking that he should be included in the list of subscribers.

The Vicar of Leeds seconded the motion. He explained, in regard to the abattoirs, that there were still a number of private slaughter-houses existing in the city, and that if the Corporation could bring pressure to bear on the owners to induce them to make use of the public abattoirs it would be an immense blessing to the city. Through lack of funds the Society had been obliged to dispense with the services of an Inspector for some two or three years past, so that more money was urgently needed if they were to carry on their work energetically. He believed that Dr. Cohen and Mr. Teale would be able to initiate a vigorous policy. The Vicar enlarged on the great good that might be done by means of leaflets, and wished it to be known that the Society's funds in hand were all required in connection with the printing and distribution of these leaflets.

The motion was agreed to.

The Rev. C. Hargrove, moved the re-election of officers and Committee, including the Bishop of Rochester as president, Dr. Trevelyan hon. treasurer, Dr. Cohen and Mr. Michael Teale hon. secretaries, and the Vicar of Leeds chairman of Committee.

Dr. Hartley seconded the motion, which was carried.

A hearty vote of thanks to Mr. Robert Jowitt and Mr. Teale for their services as hon. secretaries, and to Mr. Matthews as hon. treasurer, was passed on the motion of Mr. B. D. Marshall, and a vote of thanks was accorded to the Lord Mayor and to the Corporation for the use of rooms during the year.

In reply, the Lord Mayor said the Corporation welcomed the assistance which such a Society might render in the interests of the city.

THE MIDDEN-PRIVY AS A DISSEMINATOR OF TYPHOID.

In a summary of the insanitary conditions attending an outbreak of typhoid in York during the second half of the past year, Dr. Edmund M. Smith, the Medical Officer of Health for the city of York, blames the midden-privy as being the chief source of the contagion. He says:—

Of 171 houses affected during the second half of the year (30 at least of which were to be described as dirty), 97 possessed midden-privies, and 74 water closets.

At the midden-privy houses there occurred 124 cases, 27 being secondary to cases occurring at the same house, and five of the cases (all single cases) had undoubtedly contracted the disease outside York, so that the net number of midden-privy houses probably having something to do with the causation of fever in the city was 92 (with a net of 119 cases). The large majority of the midden-privies were more or less foul or leaking, so foul as to constitute nuisances; at 30 of the 97 privy houses there were positive defects of drainage also.

At the 74 water-closet houses there occurred 97 cases of typhoid fever, 23 being secondary to cases occurring at the same house, and not less than 12 of the cases (all single) had contracted the disease outside York, so that the net number of water-closet houses having some connection with the causation of fever in the city was 62 (with 85 cases net). Of the remaining 62 water-closet houses deduct five where there is reason to believe (there being no sanitary defects at these five houses) that the patients contracted the disease elsewhere within the city in attending upon other cases. We have now 57 to consider. Of these not less than 27 had some defects of drainage (*i.e.*, drains passing under the houses defective, drains choked, defective rain-water downspouts, defective yard-gullies). At least 16 were to be described as decidedly dirty; 10, having no defects of drainage, were distinctly associated with conditions of polluted soil, in addition to practically the whole of the 20 water-closet houses, in which were also houses dirty and houses with defective drains. In fine, there are only 15 water-closet houses in which we fail, so far, to find any clue as to the possible or probable origin of the case, there being no defects of drainage, no obvious pollution of soil, no history of possible origin, outside the city. In four only the householders complained strongly of offensive sewer ventilators.

Thirteen houses affected during 1900 had been affected with typhoid fever during the previous six years, and 12 out of the 13 were midden-privy houses, and affected midden-privies are, in my opinion, capable of affecting many other houses than those to which they belong. Practically all the privies have led to more or less pollution of the soil, and cats, mice, birds, and flies, in my opinion, play an incalculable part in the spread of contagion. In at least 87 of the 171 houses, the drain was not disconnected from the sewer or properly ventilated, and of these at least 25 of the drains pass under the house.

Rain-water downspouts:—Fifty-six were found to be

connected direct to the drain; 42 were not disconnected from the street sewer; 10 were not disconnected from the sewer, and received the waste-pipe from the roof of the bay window, immediately below a bedroom window. A large number of the fall spouts connected direct to drain or sewer were found to have open joints. In 19 instances the sink waste-pipes, or the gullies in the yard over which they opened, were untrapped or in some way or other defective. In at least 50 instances the yard-pavements of the houses were incomplete or defective, and permitting of pollution of the subjacent soil. In at least 53 instances the sewer ventilators or street gullies were complained of as acting offensively as outlets of sewer gas. Nearly every typhoid-affected house complained of either the sewer ventilators or the street gullies.

Taking the whole of the cases into consideration, I find that the majority were associated with the existence of midden-privies, most of which were more or less foul or leaking, with uncemented walls and floors, in not a few instances with dilapidated walls, most of them permitting of the pollution of the adjacent soil. The cementing of the walls and floors with many of the privies is insufficient to prevent pollution of the soil, as it is often cracked and so permits soakage; a large number of them are found inches deep in liquid filth, or so full of refuse as to reach above the cemented portion of the walls.

Furthermore, a large proportion of the midden-privies, especially in the Leeman-road, Newboro'-street, and Bishopthorpe-road districts, have become specifically infected by the excreta of typhoid fever cases in previous years. The number of these has, of course, become largely increased this year, before measures could be taken to prevent their infection, and by cases in the early stages of the disease. Next to midden-privies, defects of house drainage were most associated with the occurrence of the disease.

During the summer of 1899 the neighbouring surface sewer ventilators and street gullies were frequently acting offensively as outlets of sewer gases. The sewers were investigated and were found to possess very slight fall, and they contained extensive deposits. The sewers were therefore re-laid under improved conditions and with much better gradients, and I have heard little or no complaint of their ventilators during the summer of 1900. The work of re-laying the sewers was completed in May, 1900, some weeks before the fever commenced to affect the district.

Whether or not sewer gas had any connection with the outbreaks of typhoid fever in this district during the years 1899 and 1900 is doubtful; it is impossible to say (we have no positive evidence); it may or may not have had some influence. But when one considers the hemmed-in position of the midden-privies in the district, the number of them previously infected by typhoid excreta, and the enormous numbers of flies to be observed during the summer months playing around middens, kitchens, and pantries (cats and mice must also not be forgotten as possible carriers of contagion), I am convinced that the midden-privies of the district were the chief source of the contagion.

"In my opinion, York," says Dr. Smith, in conclusion, "is a town for which midden privies are not suitable, taking into consideration the flatness of its level, its porous, absorbent soil, its narrow streets and numerous yards or courts. It is pre-eminently a town for the water-carriage system throughout, although that system, it must be said, calls for perfect drainage, and for free ventilation of the sewers."

The Tamworth Town Council has decided to build a number of cottages under the Housing of the Working Classes Act.

ANNUAL REPORTS.

Auckland.—The annual report of the Medical Officer (Dr. McCullagh) shows that during the year there has been 265 deaths in the town, 49 of which occurred in the workhouse. Of the deaths in the workhouse 29 belong to the town, and 20 to the rural districts. The death-rate for the year was 19·2, as compared to 22·5 for the previous year. Seventy-two of the deaths were those of children under one year of age, giving an infant mortality rate of 193, an improvement on the previous year, when the rate reached 220. The zymotic death-rate was 2·003, as compared with 4·7 for the previous year. There were thirteen deaths from various forms of cancer. There were 33 cases of enteric fever notified, as compared with 157 in 1899. He appends a list of enteric fever cases in the whole county, and from it he adduces the moral that there was a common cause for enteric fever in the eastern portion of the county of Durham. When the cases increase in the whole county there is an increase in Auckland, and when the disease diminishes in the county it diminishes in Bishop Auckland. And the only common cause which has been pointed out is the presence of privy-middens, defective drains and sewers, and the necessary accompaniment of polluted soil in close proximity to dwelling-houses. The almost entire absence of enteric fever from houses provided with water-closets has again been most marked. During the past year the water supply has been most satisfactory, and the filter bed has acted well. With a second filter and larger storage the risk of any contamination will be reduced to a minimum. The report concludes by paying a compliment to Mr. Sanderson, the Sanitary Inspector.
